PROTECTIVE SKIN COATINGS FOR THE PREVENTION OF SUNBURN

MATTHEW LUCKIESH, D.Sc.; A. H. TAYLOR,
H. N. COLE, M.D.,
and
TORALD SOLLMANN, M.D.
Cleveland

In December 1942 the Council on Pharmacy and hemistry was approached by Col. Otis O. Benson Jr., . C., representing the commanding general, Army ir Forces, Matériel Center, Wright Field, Dayton, hio, in regard to the most effective protective subance for the prophylaxis of sunburn. The problem as as follows:

> The Matériel Center would like information on the most fective protective substance for the prophylaxis of sunburn. n essence, the problem is as follows:
>
> (*a*) Men marooned on life rafts or in the desert following rplane crashes for various reasons seem to lose a good deal of their clothing and are subject to severe solar exposure.
>
> (*b*) It has been definitely established that a protective subance (cream or ointment) to be stowed in life rafts and other mergency equipment in military aircraft is required, when he aircraft is operating in the southwest Pacific and Mediterranean theaters.
>
> (*c*) The requirement per seven-man life raft has been tentavely set at enough protective ointment to make four applicaons to at least 25 per cent of the body surface, for nine men. 'erhaps it might be better to consider four applications to 5 per cent of the body surface per man, with the necessity of ncluding seven to nine such units in a large airplane.
>
> The substance used must, of necessity, be nontoxic and might ven, on the other hand, be either bacteriostatic or bactericidal. urther problems are:
>
> (*a*) Maximum protection per unit weight and/or volume.
>
> (*b*) Maximum skin coverage per unit weight and/or volume.
>
> (*c*) Stability and freedom from rancidity of the substance o be used.
>
> (*d*) This substance should lend itself to simple packing, and f freezing were to occur at high altitudes, the container should not burst.
>
> (*e*) The protective substance is to be put up in suitable containers and stowed in life rafts, which, in turn, are in stowage compartments of the airplane and are jettisoned at the time of forced landing on water (or even in the desert).
>
> It is specifically requested that this inquiry not be published in any form in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.[1]
>
> Your cooperation and aid in this matter will be deeply appreciated.

It was decided to obtain the cooperation of the Lighting Research Laboratory of the General Electric Company, Nela Park, Cleveland. This laboratory, under the direction of Dr. Matthew Luckiesh, a world-wide authority on light and radiant energy, is ideally equipped to make quantitative spectral measurements and to elucidate any physical problems associated with compounds to be investigated. Unfortunately, in the past, the numerous preparations suggested for prevention of sunburn have been too often selected with little or no study or real attempt to see what the effect of the compound would be on the ultraviolet energy of various wavelengths that cause sunburn. Probably as serious an endeavor to answer this problem as can be found in the literature is the one by Bachem and Fantus.[2] They made spectroscopic studies of their individual compounds and then followed these up with limited biologic studies on the human body to analyze the protection of the preparations against exposure to the sun's rays. Their conclusions were that: 1. Wool fat, yellow petrolatum and diachylon ointment have the highest sun-screen value of the ointment bases tested. 2. Yellow petrolatum is superior to white petrolatum for protection against ultraviolet rays. 3. Titanium dioxide is the most efficient of the insoluble powders tested so far as sunscreen value is concerned. Calamine is also of value but is less efficient. 4. Ichthammol has a definite sun-screen value even in concentration as low as 2 per cent, and this may explain in part its therapeutic value. 5. Aesculin and menthyl salicylate are more efficient than is quinine oleate.

While this article was of definite value and gave some good leads, it did not present measurements of the absorption of energy of various wavelengths that cause sunburn. Spectroscopic studies may do this roughly, but a careful evaluation can be made only by quantitative measurements for various wavelengths of ultraviolet energy.

Erythema, or sunburn, as a result of exposure to natural sunlight is principally caused by ultraviolet energy in the spectral range 2,900 to 3,200 wavelengths. (These wavelengths are expressed in angstrom units.) Consequently any satisfactory protective cream should be highly absorbent in this spectral region. Another requirement is that the material shall not be easily washed off the skin.

Previous researches by Luckiesh and Taylor[3] show the relative effectiveness of certain lines of the mercury spectrum in the solar spectral region of special interest (table 1).

From the Lighting Research Laboratory, General Electric Company, Nela Park, Cleveland, and from the Department of Dermatology and Syphilology and the Department of Pharmacology and Experimental Therapeutics of Western Reserve Medical School and of the University Hospitals.

[1] Now that hostilities have ceased, the authors have been given permission to publish the results of their investigation

In order to measure the spectral transmission of a thin film of specimens of protective material, a thin wedge was formed between quartz plates. In some cases it was quite difficult to obtain wedges free from air bubbles, which are more transparent than the test material. Heating the quartz plates before applying the material made it flow out better. Since some of these materials diffuse the transmitted energy, it was necessary to make the transmission measurements with fused quartz, ground on both sides, in front of the slit of the monochromator.

ARTICLES TESTED

After preliminary discussion with Dr. Luckiesh, it was decided to test out Harriett Hubbard Ayers' Sun Tan, titanium dioxide, phenyl salicylate, zinc oxide, petrolatum flavum U. S. P., amber petroleum jelly, petrolatum album U. S. P., unguentum zinci oxidi and Cuticolor titanium dioxide, which contains, in addition to the titanium dioxide, the ferric and ferrous oxides to add color to the compound.

For reference purposes these materials were assigned designation letters. The compositions of the various materials tested are given in table 2, and the transmissions of various thicknesses in table 3. Later, in view of the results with the several petrolatums, it was thought best to explore this angle more fully and through Mr. Trevor Holliday, president, Standard Oil of Ohio, the problem was taken up with Mr. F. H. Bedford Jr., Standard Oil of New Jersey, New York City. He forwarded for the study the following materials:

TABLE 1.—*Effectiveness of Mercury Spectrum*

Wavelengths	Relative Effectiveness in Producing Erythema and Tan
2,967	1.00
3,022	0.50
3,130	0.02
3,342	0.004
3,650	0.0012

Specimen O. Extra light amber petrolatum, Parmo number 1736.

Specimen P. Amber Parmo (petrolatum U. S. P.) number 2356.

Specimen Q. Dark Red Vet. Petrolatum.

Specimen R. D and R sun lotion, containing menthyl salicylate.

Specimen X. U. M. BM = C Petrolatum. (This was a dark, heavy petrolatum, too stiff to be used on the skin and therefore not tested.)

In addition, on suggestion of Prof. Paul Hanzlik, pharmacology department, Stanford University Medical School, a trial was made of:

Specimen S. "Sunex" Ointment (Abbott Laboratories, Chicago), containing butesin, metaphen and oleic acid ester amide diethylamine in cold cream. Professor Hanzlik stated that this compound is used quite widely on the deserts and mountains on the Pacific coast, with good results. He also mentioned petrolatum.

The transmission of ultraviolet energy of various wavelengths in the solar spectrum is presented in table 4 for specimens O, P, Q, R and S.

During the past seven years Luckiesh and Taylor have made many measurements of the ultraviolet in daylight in Cleveland, including a continuous integration of the erythemal ultraviolet energy. The maximum intensity measured in a four year period, occurring near noon, was equivalent in erythemal value to approximately 42 microwatts per square centimeter at wavelength 2,967.

In order to provide a greatly accelerated test of the protective creams, they used a clear-bulb type S-1 lamp without reflector. This source emits no appreciable energy shorter than wavelength 2,800. By means of quartz lenses, an image of the arc was projected onto a ¼ inch hole in a metal diaphragm. A quartz water-cell was placed in the optical path to absorb most of the heat in the beam. The energy passing through the hole was measured and found to be sixty times the erythemal value of the highest intensity of sunlight and skylight measured in the four year period. Thus one minute exposure to this source was equivalent

TABLE 2.—*Composition of Sunburn Protective Materials*

Specimen A	Gm. or Cc.
Titanium dioxide	20.0
Liquid petrolatum	10.0
Wool fat anhydrous	11.5
Petrolatum flavum	36.5
Water	22.0
Specimen B	
Titanium dioxide	15.0

* Four different specimens from same lot. Variations apparently due to nonuniformity of mixture of the two ingredients.

to one hour of the most intense sunlight in Cleveland in a four year period. This was computed to be sufficient to produce a minimum perceptible erythema on average untanned skin in approximately eight seconds. The unprotected untanned skin of several subjects was exposed for fifteen seconds each to this intensity, and all developed some erythema from the exposure, most of them appreciably more than the minimum perceptible, thus confirming the energy measurement.

To provide the maximum protection it is desirable to have the protective coating so opaque to the erythemal region of the spectrum that a thin coating will give complete protection over many hours of continuous exposure. Most of our erythemal tests have been made with thin coatings, though some tests were made with thicker coatings, all on the upper arms of the subjects. Some detailed results of these tests are presented in table 5.

The terms "thin coating" and "thick coating" are rather indefinite as descriptive of the thickness of these creams, but the former indicates a coating which has been rubbed out quite well, corresponding to the thinnest coating which is likely to be applied.

WASHING EXPERIMENTS

Specimen C (titanium dioxide, glycerin and vanishing cream) and F (phenyl salicylate 10 per cent in unguentum zinci oxidi) wash off readily, and these are not suitable for the purposes desired. Harriett Hubbard Ayers' Sun Cream easily washes off the skin. Likewise R (D and R sun lotion) furnished by the Standard Oil Company of New Jersey, containing menthyl salicylate, is found to be easily removed from the skin by slopping water over it.

Table 4—*Percentages of Ultraviolet Energy of Various Wavelengths Transmitted by Four Specimens of Petrolatum and Sunex Ointment*

Specimen	Thickness, Mm.	Per Cent Transmission at Wavelengths				
		2,967	3,022	3,130	3,342	3,650
O	0.03	32	32	55	88	94
P	0.03	25	30	44	74	89
Q	0.03	0	0	1.8	16	58
R	0.03	13	16	23	56	71
S	0.04	26	31	43	—	—

All other preparations adhere well to the skin after water has been repeatedly slopped over them, and Q (dark red vet. petrolatum) adheres most tenaciously to the skin and is hardly removed with soap and hot water and scrubbing.

FREEZING EXPERIMENTS

It was not found feasible to test the various compounds at very low temperatures, but they were all placed in the freezing compartment of a refrigerator at — 3 F. for four days.

Specimens A and G contained titanium dioxide, liquid petrolatum, anhydrous wool fat, petrolatum flavum and water, and C contained in addition phenyl salicylate.

Microscopically before freezing they showed a rather uniform picture. After four days in the freezing compartment of the refrigerator the collapsible full tubes were covered with hoar frost and were stiff, and only after some twenty minutes at room temperature was it possible to express some of the contents for examination. Microscopically, with both low and high power, the field showed the uniform picture to have disappeared

Table 5—*Results of Erythemal Exposures to Determine Protective Qualities of Various Preparations*

Ultraviolet intensity of source equivalent to sixty times the most intense sunlight measured in Cleveland over a period of four years. One minute exposure to this source is equivalent to one hour of the most intense sunlight referred to, and about two hours of average midsummer noon sunlight in Cleveland.

Subjects B and H

No cream, 15 seconds' exposure, well above minimum perceptible erythema (MPE).
Cream A, thin coat, 15 minutes, very strong erythema.
Cream B, thin coat, 15 minutes, mild erythema
No cream, 30 seconds, strong erythema but less than cream A with exposure of 15 minutes

Subject F

No cream, 15 seconds, well above MPE
Cream B, thin coating, 15 minutes, very strong erythema.
Cream B, heavy coating, 20 minutes, no erythema except at edge of spot exposed, where cream was apparently scraped very thin against diaphragm
Cream D, thin coating, 15 minutes stronger than 15 second exposure without cream, slightly less than 30 second exposure without cream.
No cream, 30 seconds, strong erythema but less than cream B exposed 15 minutes.

Subject H

No cream, 15 seconds, moderate erythema, probably at least double or treble MPE
Cream G, thin coating, 15 minutes, erythema more than 30 second exposure without cream.
"Sun Cream," Harriett Hubbard Ayres' preparation, thin coating, 15 minutes, about same as 15 second exposure without cream.
No cream, 30 seconds, very strong erythema.

Subject W

No cream, 15 seconds, moderate erythema, approximately double MPE
Cream B, thin coating, 15 minutes, about same as 30 second exposure without cream
Cream E, thin coating, 15 minutes, somewhat stronger erythema than 30 second exposure without cream.
No cream, 30 seconds, strong erythema

Subject M

No cream, 15 seconds, MPE
Cream J, thin coating, 15 minutes, erythema only at one edge of exposed spot, probably due to cream being scraped off by edge of diaphragm
Cream J, thick coat, 20 minutes, no erythema
No cream, 30 seconds, strong erythema

Subject B

No cream, 15 seconds, moderate erythema
Cream J, thin coating, 20 minutes, less erythema than 15 second exposure without cream Apparently less inflammation and more direct tanning
Cream L, thin coating, 20 minutes, about same as 30 second exposure without cream
No cream, 30 seconds, fairly strong erythema.

Subject K

No cream, 15 seconds, fairly strong erythema.
Cream J, thin coating, 30 minutes, moderate erythema, but less inflammation than 15 second exposure without cream. Apparently some direct tanning
Cream L, thin coating, 30 minutes, slightly more erythema than with cream J.
No cream, 30 seconds, strong erythema
After 2 days all spots appeared to be about equally inflamed.

No cream, 10 seconds, strong erythema
Cream D, thin coating, 20 minutes, strong erythema.
Cream L, thin coating, 20 minutes, strong erythema
No cream, 20 seconds, strong erythema

To test further the relative merits of creams D, J and L, 3 subjects were given thin coatings of these three creams and exposed for 15 minutes each, with the following results

- No cream, 10 seconds
  - Subject B, strong erythema.
  - Subject F, no erythema
  - Subject W, moderate erythema.
- Cream D, 15 minutes.
  - Subject B, no erythema
  - Subject F, strong erythema.
  - Subject W, strong erythema, at least as much as 20 second exposure without protective cream
- Cream J, 15 minutes
  - Subject B, weak erythema, slightly greater than MPE, apparently some direct tanning
  - Subject F, mild erythema, very little inflammation, apparently some direct tanning.
  - Subject W, very faint erythema or tanning.
- Cream L, 15 minutes
  - Subject B, strong erythema, about same as 10 second exposure without cream
  - Subject F, some erythema, but less than 20 second exposure without protective cream
  - Subject W, very mild erythema, slightly above MPE
- No cream, 20 seconds
  - Subjects B and W developed strong erythema, but subject F developed only a moderate erythema.

and varying sized irregular "lakes" indicated that the water in the compound had separated from the mixture—rendering it less suitable for use and probably precluding the use of this type of a base, even if the preparation was found to be of value otherwise. Since these bases are of the so-called cold cream type ordinarily made up in pharmacies, their use would be contraindicated for any preparation selected, since the water would be laked out of the compound in freezing and there would no longer be the uniform character so necessary to screen off and absorb the ultraviolet energy.

The other preparations do not seem to change from use of the aforementioned temperatures. It is true that in collapsible tubes[4] the contents are congealed and require a little warming and manipulating before one is able to express them. None of the tubes showed evidence of bursting. It is a question whether this would be true at extremely low temperatures, particularly with preparations of the cold cream type.

Perhaps it would be advisable to use plastic containers because of the scarcity of tin. Glass containers should not be employed because of the danger of splintering in breakage.

Specimen Q is rendered much stiffer by freezing, but by sufficient manipulation and warming, such as it would receive in the tropics, it should lend itself well to application on the skin, even after it has undergone low temperatures from high altitude flying.

SPECTRAL TRANSMISSIONS

As previously mentioned, the only rays pertinent to this study are wavelengths 2,967 and 3,022. The percentages of ultraviolet energy of various wavelengths transmitted by the various protective coatings are given in tables 3 and 4.

Moreover, specimens A, B and G, containing titanium dioxide, may be immediately eliminated because of the tendency for the water to separate out on freezing. Specimens C (titanium dioxide in vanishing cream base), F (phenyl salicylate in unguentum zinci oxidi), Harriet Hubbard Ayers' Sun Cream and specimen R (D and R sun lotion) are eliminated at once because they are so easily washed from the skin.

As to the bases to be employed, freezing experiments have already shown that there should be no water in the compound. Unguentum zinci oxidi does not serve well as a base—it washes off too easily. Moreover, it contains white petrolatum, which is not a good screen. Comparison in table 3 of M (petrolatum flavum) and of N (petrolatum album) shows that the yellow petrolatum alone is eight to ten times as efficient a screen as is the white variety. Another specimen of petrolatum flavum, H, was apparently more refined and not such a good filter. Consequently, further investigation was made of petrolatum flavum samples O, P and Q, from Standard Oil Company of New Jersey (table 4). Both O and P, refined compounds, showed high transmission, 25 to 32 per cent, in the two wavelengths, but Q (dark red vet. petrolatum) was opaque to both wavelengths—in fact it was practically selectively opaque to the wavelengths causing sunburn.

Study of table 3 further reveals that, while titanium dioxide as used in specimens A, B, G and K acted relatively well in preventing transmission of wavelengths 2,967 and 3,022, it did not act as efficiently as phenyl salicylate (salol) in specimens D, J and L. With phenyl salicylate in D (10 per cent phenyl salicylate and 33⅓ per cent zinc oxide in petrolatum flavum) there was no transmission. In specimen J (10 per cent phenyl salicylate in petrolatum flavum) (five examinations) transmission varied from extremes of 6.8 per cent down to 0 at wavelength 2,967, with a mean of 1.5 per cent, and at wavelength 3,022 extremes of 5.9 per cent to 0 and a mean of 0.8 per cent. In specimen L (10 per cent phenyl salicylate and 15 per cent zinc oxide in petrolatum flavum) transmission in thickness of 0.03 mm. was 0.02 per cent at wavelength 2,967 and 0.04 per cent at wavelength 3,022. With a thickness of 0.06 mm. it was entirely zero. As zinc oxide also was present in D and L, the query might be raised as to its value. Phenyl salicylate was present in all these. Specimen E was 33⅓ per cent zinc oxide in petrolatum flavum and the transmission was very low, being 2.2 per cent at wavelength 2,967 in thickness of 0.03 mm. and 0.18 per cent in thickness of 0.06 mm. The transmission at wavelength 3,022 was 3.0 per cent in the thinner and 0.3 per cent in the thicker preparation. Undoubtedly, zinc oxide is not to be ignored as an ultraviolet light filter, and too it has the added advantage of showing where it has been applied. Luckiesh and Taylor have used it in paints for many years for the absorption of ultraviolet. From the standpoint of spectral studies, perhaps, it could be profitably added to a 10 per cent phenyl salicylate in petrolatum flavum—unless it would make the compound too thick and too dry, which would be the case if it was to be added to specimen Q as a base.

Specimen R (D and R sun lotion) containing menthyl salicylate in a thickness of 0.03 mm. gave spectral transmission of 13 per cent in wavelength 2,967 and 16 per cent in wavelength 3,022, while "Sunex" Ointment, Abbott Laboratories, in a thickness of 0.04 mm. gave an even higher transmission, 25 per cent at wavelength 2,967 and 31 per cent at wavelength 3,022. Obviously, both compounds are far too high to be of much value.

ULTRAVIOLET PROTECTION TO THE HUMAN SKIN OF VARIOUS COMPOUNDS

In these experiments of Luckiesh and Taylor on six different subjects there was used an ultraviolet source intensity equivalent to sixty times the most intense sunlight measured in Cleveland over a period of four years. One minute exposure to this source is equivalent to one hour of the most intense sunlight referred to and comparable to about two hours of average midsummer noon sunlight in Cleveland.

While nearly all the specimens were tried out, A, B and G may be eliminated from pertinent discussion because of the throwing out of the water contained in them after undergoing freezing. We may also eliminate C, suggested by Prof. Paul Hanzlik, and F, since they were readily removed from the skin by the washing experiments. Also Harriet Hubbard Ayers' Sun Cream and specimen R (D and R sun lotion), containing menthyl salicylate, are easily washed off. Specimen K (titanium dioxide in petrolatum flavum) was deleted because of the somewhat unsatisfactory results in the spectral transmission experiments. At least Luckiesh and Taylor did not deem it worth investigating further in actual erythemal tests in view of the experiments with A, B and G in which titanium dioxide was used. The results obtained with typical subjects for the various coatings are presented in table 5.

---

[4] Mr. F. W. Treber, of the Miller Drug Company, Cleveland, furnished collapsible tubes and prepared the compounds in them for these experiments.

Specimen O (extra light amber petrolatum), specimen P (amber parmo [petrolatum U. S. P.]), specimen R (D and R sun lotion) and "Sunex" Ointment were not tested biologically because of their high spectral transmission for wavelengths 2,967 and 3,022.

The most interesting result in the entire series was the biologic test with specimen Q (dark red vet. petrolatum). The exposure of ten seconds on the subject, without any protection, produced a moderately strong erythema, while a twenty minute exposure produced no visible erythema when the same subject had a thin coating of the compound. This exposure was equivalent to twenty hours of the strongest sunlight in Cleveland measured during a four year period. It is quite evident that this petrolatum alone, with nothing added, would give ample protection to the skin. Moreover, the petrolatum rubbed into the skin of one of us several nights in succession gave no evidence of irritation. Dr. E. B. Hunn, chief chemist of Stanco Inc., reported that "the compound is a refined grade of petrolatum, nonirritating even to a sensitive skin. It is neutral in reaction and will conform to the U. S. Pharmacopeia test for freedom from alkali and mineral acids. It is also free from anthracene derivatives, as it is derived from a particular crude oil which is said to be essentially free of anthracene derivatives; and, secondly, any trace of such derivatives in the crude would be removed in the refining process which includes filtration of the product through fullers' earth."

Review of the foregoing data indicates that phenyl salicylate, which is present in D, L and J, apparently plays a great role in prevention of sunburn, for in cream J it is the only constituent added to the petrolatum flavum. In fact, better results are achieved with J than with D and L when zinc oxide is added, 33⅓ per cent in D and 15 per cent in L. Apparently the zinc oxide may even act as a deterrent to phenyl salicylate, for results are not as good as in phenyl salicylate cream. Perhaps the zinc oxide coats the phenyl salicylate particles.

COMMENT

It is obvious from the washing experiments that any compound selected must be of a character that will adhere quite well to the skin even though waves wash over the subject or even though he is occasionally immersed. This immediately ruled out all preparations in a vanishing cream base or so-called cold cream bases. It also deleted "Sunex" Ointment, D and R sun lotion, 10 per cent phenyl salicylate in unguentum zinci oxidi and Harriet Hubbard Ayers' Sun Cream. Specimen Q (dark red vet. petrolatum) satisfies this requirement admirably. It is very difficult to remove it even with soap and water and scrubbing.

Again, the compound must not be broken down by exposure to low temperatures—this almost at once eliminates all greaseless creams and ordinary cold creams with their water content.

The compound should be as simple as possible and, other things being equal, as easily procured and as inexpensive as possible. The dark red vet. petrolatum again answers these demands.

It should be packed in nonbreakable containers, which should not burst if frozen. Our lowest temperature experiments were —3 F., which did not break the collapsible tube containers of even cold cream base compounds containing water. With temperatures of —30 to —40 F., this might not be the case if there was water in the cream.

There are further essentials necessary in picking a suitable compound. The compound should not become rancid. The compound should lend itself to simple packing and, with the scarcity of tin, perhaps plastic containers would serve the purpose, though collapsible containers are preferable as the preparation would be kept clean and free from dirt, contamination and contact with sea water and sand.

The compound should be free from toxicity and, since phenyl salicylate has been found to be of value, the query arises as to its toxic properties and phenol absorption. For this purpose a 20 per cent phenyl salicylate in petrolatum flavum U. S. P. (i. e. twice the strength of the compound advised) was rubbed into the skin of the right half of the body, excluding the scalp, of 4 hospital patients whose blood urea nitrogen and urinalysis were normal. The unguentum was rubbed in the same region on four successive nights; no bathing was done during this time. Testing of the specific gravity for albumin and of the sediment microscopically was done on the urine after each of the last three applications of the salve; a blood urea nitrogen test was done the day after the last application. At no time did investigation of the urines show any evidence of irritation of the kidneys, nor was there any appreciable rise in the blood urea nitrogen. Ethereal sulfate determinations were made on twenty-four hour urine specimens on the last two days of the investigation. Dr. Ramon Hanzal of the Biochemistry Laboratory of the Institute of Pathology of Western Reserve University School of Medicine made these determinations to indicate the presence of increased phenol excretions. He employed the Folin method, and in none of the 4 patients was there a significant effect on the level of ethereal sulfates excreted in the urine.

The results of the physical and biologic investigations of Luckiesh and Taylor, along with clinical experience, allow certain deductions. The experiments show that titanium dioxide is not a very dependable protective agent, at least specimen K (20 per cent titanium dioxide in petrolatum flavum) did not indicate it in spectral experiments. And in biologic experiments specimens A, B and G, containing titanium, did not compare favorably with other less complex preparations. Zinc oxide is of definite value in preventing sunburn. Menthyl salicylate as tested in specimen R (D and R sun lotion) was not a particularly good agent, nor was "Sunex" (Abbott Laboratories—butesin, metaphen and oleic acid ester amide diethylamine in cold cream). Yellow petrolatum has dependable screening power against ultraviolet energy at wavelengths 2,967 and 3,022, in fact far more than more refined white petrolatum. Specimen Q (dark red vet. petrolatum, the Standard Oil Company of New Jersey) is opaque to these rays and likewise completely protected the skin of a subject to a dose of twenty minutes' exposure, equivalent to twenty hours of the strongest sunlight in Cleveland measured during a four year period. No doubt this simple compound may be employed alone in aviation and naval work as a satisfactory protection from sunburn. But in view of the excellent results with phenyl salicylate we are inclined to recommend that a Kit A be prepared with the dark red vet. petrolatum alone and a Kit B containing the dark red vet. petrolatum plus 10 per cent phenyl salicylate. Both should be tried out and comparisons made.

SUMMARY

1. Most of the erythema resulting from exposure to natural sunlight and skylight is produced by ultraviolet energy shorter than wavelength 3,200.

2. The Army Air Forces desired an agent or agents as a prophylaxis of sunburn. This protective cream or ointment to be stowed in life rafts or military aircraft must have maximum protection per unit weight or volume. It must be stable to heat and cold, free from rancidity, lend itself to simple packing, be nontoxic and not wash off.

3. Experiments were carried out at the Lighting Research Laboratory, General Electric Company, Nela Park, Cleveland, to ascertain the safest, most practicable, most cohesive, nontoxic agent or agents to serve this purpose.

4. Dark red vet. petrolatum (Standard Oil Company of New Jersey) was found to be quite opaque to erythemal energy. It likewise served as a complete protection to the skin in an exposure equivalent to twenty hours of the strongest sunlight in Cleveland measured during a four year period. This product in itself is recommended for the protection of aviators marooned on life rafts or in the desert following airplane crashes. The compound is not irritating and adheres tenaciously to the skin.

5. Phenyl salicylate (salol) was also found to be an excellent protection from ultraviolet radiation when put up in a 10 per cent cream. Experiments have also shown it to be nontoxic. It is further felt that a 10 per cent phenyl salicylate incorporated in the dark red vet. petrolatum be also tried as a suitable agent for protection of marooned aviators.

HEPATOLENTICULAR DEGENERATION

F. HOMBURGER, M.D.,
and
HARRY L. KOZOL, M.D.
Boston

Hepatolenticular degeneration is a rare, progressive and fatal disease characterized by extrapyramidal signs, degenerative changes in the basal ganglions, cirrhosis of the liver and pigmentation of Descemet's membrane at the limbus of the cornea (Kayser-Fleischer ring).

Denny-Brown[1] in a recent review of this subject has pointed out that the work of Hall[2] in establishing the identity of Wilson's disease (progressive lenticular degeneration) and Westphal-Strümpell's disease (pseudosclerosis) has obscured the remarkable differences between the two syndromes. There can be no doubt that the two groups are closely related and should be considered as aspects of the same disease process. To that extent Wilson's attempt to absorb pseudosclerosis into his group of "progressive lenticular degeneration" may have been justified. However, in the cases described by Wilson and most English and American authors the postural changes were prominent and cases with tremor and without postural changes were largely overlooked, although this group had been described by Westphal[3] and Strümpell[4] as "pseudosclerosis" (1883 and 1898). In 1912 von Hösslin and Alzheimer[5] demonstrated diffuse gliosis in pseudosclerosis and in 1909 and 1912 Fleischer[6] noticed the constant occurrence in pseudosclerosis of a golden brown pigmentation in Descemet's membrane at the limbus of the cornea and of cirrhosis of the liver.

Wilson[7] in 1912 published his classic paper, describing the constant association of cirrhosis of the liver with a progressive extrapyramidal disorder which included tremor, postural states, contractures, athetoid movements, rigidity, dysarthria, dysphagia and psychotic symptoms. Although such a description is wide enough to include the clinical features of pseudosclerosis, cases of the latter variety may present a picture far different from those described by Wilson, particularly in the lack of postural and contractural disorders. Wilson described a gross degeneration of the lenticular nuclei, obvious to the naked eye in his cases. This has been found in many cases involving a short course with contractures and postural difficulties. However, it has been well demonstrated that corresponding to the diversity of signs there are also variations in the pathologic manifestations of the disorder. Two clearly defined pathologic extremes exist, namely gross cavitation of the lenticular nuclei (progressive lenticular degeneration of Wilson) on the one hand and, on the other, only the microscopic gliosis described by Alzheimer in pseudosclerosis. Hall[2] in 1921 recorded an intermediate case in which both gliosis and gross lenticular degeneration were present. Hall made it clear that his proposed term of "hepatolenticular degeneration" should include all these variations.

Little is known of the etiology and pathogenesis of hepatolenticular degeneration, and relatively few cases have been investigated with modern methods. In the present study special attention was devoted to the hepatic features of the disease in the hope of gaining more knowledge of the mechanisms involved in the causation of the disturbance.

Certain dietary measures were felt to benefit these patients and are offered here as a therapeutic suggestion.

REPORT OF CASES AND DATA OF CLINICAL INVESTIGATION

Case 1.—N. R., a Jewish youth aged 18 years, of Russian parentage, was first seen for trembling of the hands in March 1944. He had been referred for psychotherapy, as the variability of the tremor suggested a psychogenic origin. Discovery of the Kayser-Fleischer ring led to the diagnosis of hepatolenticular degeneration. The patient's illness had begun insidiously with tremor of the hands about two years before he was first seen. He was a student of drafting and became first aware of clumsiness and incoordination in handwriting (fig. 1) and drawing, especially in his right hand. Gradually tremor of his arms appeared, complicated by a choreic component and jerky impairment of voluntary movements These symptoms dis-

appeared during sleep, were hardly noticeable at rest and were greatly exaggerated by motion. The jerkiness of voluntary movements was also manifested in the lower extremities by an awkward, loose, flinging, tremulous gait. His speech became nasal and reflected awkwardness in voluntary movements of his tongue and accessory palatine musculature as well as tremor. He also complained of hypersalivation but never of rigidity. His emotionality increased, but there was no intellectual deterioration. Despite partial remissions, some of which lasted for several months, he had grown gradually worse.

The patient's parents were first cousins. The father died at the age of 40 of heart disease. The mother was living and well. She had a pes cavus on the left and no other deformities or diseases. There were 3 children in the family, all of whom had hepatolenticular degeneration (cases 2 and 3). There was no history of any neurologic disease in the direct or collateral ancestry except for an uncle (father's brother), who is said to have been unable to take pictures with a camera because of the tremor of his hands. The information available is limited and the family history is incomplete.

The past history revealed common childhood diseases and no history of brain involvement, jaundice or right upper quadrant pain. There had been episodes of "upper respiratory infection," often accompanied by abdominal distress and vomiting, usually of short duration and sometimes requiring bed rest. On all of these occasions there was anorexia for several days. The patient was born and spent his life in a well populated middle class section of the city. No toxic factors were discovered in the patient's surroundings. The family's diet at all times had been varied and made up of about 2,400 calories (carbohydrates 285 Gm., proteins 111 Gm., fat 91 Gm.).

Physical examination showed pronounced myopia and typical Kayser-Fleischer ring in Descemet's membrane of the cornea. Examination of the head and thorax was negative except for slight sinus arrhythmia and a soft systolic murmur at the apex of the heart. The right shoulder was slightly higher than the left. The abdomen was flat with the liver palpable one to two fingerbreadths below the costal margin in the right midclavicular line. The spleen was enlarged to percussion and its lower pole palpable below the costal margin. The genitalia were small for the patient's age, but the pubic hair was well developed and the testes, though small, were of normal consistency. There was a bilateral pes cavus.

Neurologic examination showed a friendly, tall, thin boy with a wide eyed staring expression. He was bright and alert but showed a striking pleasure in telling pointless stories in the middle of a clear and reasonable conversation. There was an overall motor restlessness with a choreiform element in the muscles of the face, arms and trunk. He was never physically or mentally relaxed. When he attempted to smile there resulted a jerky, wry grimace. Except for his wide eyed expression, his face showed nothing suggestive of parkinsonism. A gross rhythmic tremor with a rate of 4 to 6 per second was present in the arms under postural tension and, at times, involved the trunk. This tremor, in the upper extremities, was complicated by a choreic element. Active movements of the arms enhanced the tremor, and extension of the arms caused wide flapping movements of the hands at the wrist joints and rhythmic flexions of the fingers. Coordination in the arms was impaired by tremor and jerkiness, and, while the finger could be accurately approximated to the nose by a series of jerky movements, a gross tremor prevented its being kept in the desired position. At times there were mild dystonic movements of the trunk. Cogwheel rigidity was observed in all joints on passive motion. The motor signs were less pronounced in the lower extremities, where there was little resting tremor but some tremor of motion and sustention. Tremulousness and rigidity caused incoordination in the use of the legs and feet. This became most pronounced when the patient turned suddenly. His stature was erect with the patient appearing to lean slightly backward as if compensating for a propulsion component. The cranial nerves were not remarkable, but the speech was slurred and nasal. All tendon reflexes were weak, and the right patellar jerk and both achilles tendon jerks were absent. The response to plantar stimulation was flexor. The abdominal reflexes were active. Sensory examination was negative.

The diagnosis of hepatolenticular degeneration having been made, a high caloric diet rich in proteins and carbohydrates and poor in fat was prescribed and the patient was discharged. Exacerbation of the tremor accompanied by nausea and vomiting with anorexia lasting for two weeks during which the patient lost 6 pounds (2.7 Kg.) prevented him from ever starting to take his diet. Torsion spasms of the trunk to the right occurred; first once or twice a day, then every hour and, three weeks after discharge, at the time of readmission, continuously, at intervals of ten minutes, lasting five to ten minutes. The patient was well aware of these seizures, describing them as accompanied by complete loss of will power.

Physical examination was essentially unchanged, but the tremor was increased and lateral nystagmus was observed. There were headaches, and a defect of convergence was found. The liver seemed smaller than previously but within normal limits.

The patient was given a diet consisting of 733 Gm. of carbohydrate, 208 Gm. of protein and 22 Gm. of fat (3,692 calories) and within five days he gained 2½ pounds (1.1 Kg.). Torsion spasms and nystagmus disappeared. On the eighth day of this regimen the patient complained of right upper quadrant heaviness and pain, constipation, nausea, anorexia and vomiting, and he refused all food. There were headaches and weakness, and the patient insisted that this episode resembled the many he had had during past years and which had been called "colds" or "grip." Intravenous administration of amino acids in dextrose solution was necessary, but within a few days and with atropine to combat the nausea the patient was again able to receive his meals and improved steadily during one month. It became possible for him to perform several simple skilled acts which he had been unable to execute for months, such as cleaning his glasses and opening doors and windows. With his general health much improved and all liver function tests (except the cephalin flocculation) negative, the patient was seen fit to undergo a liver biopsy, which was performed by Dr. Andrew Mason under spinal anesthesia and following intravenous infusion of 100 Gm. of dextrose. The patient was given light food and in addition intravenous dextrose with amino acid mixtures as well as subcutaneous injections of synthetic vitamin K-like substance and thiamine, riboflavin, pyridoxine, calcium pantothenate and niacinamide. Urinary retention and intestinal atonia were relieved by catheterization and by physostigmine and enemas. Although no infection was detectable, the patient's temperature on the fourth postoperative day reached 102 F. With the white blood cell count, urine sediment and chest plate remaining negative, the temperature rose to 106.2 F. on the fifth postoperative day and the patient became comatose. Rapid intravenous infusion of 20 per cent dextrose brought the patient back to consciousness, but there remained a variable degree of stupor, inability to articulate and to swallow and a paralysis of the upward gaze. There was a progressive increase in the amplitude and frequency of the tremor, which subsided merely during short moments. As the coma which had responded

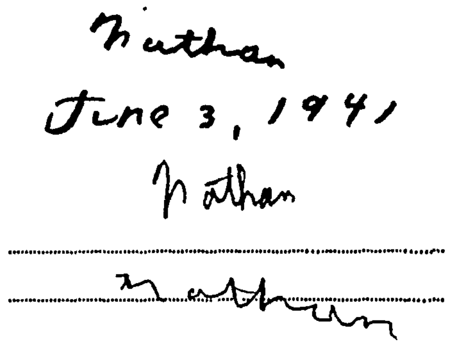

Fig. 1.—Samples of handwriting in case 1. From top to bottom: In 1941, no disease manifest; in 1944, when first seen; six months later.

so well to large doses of dextrose was interpreted as hypoglycemia due to liver failure, large amounts of amino acids, dextrose and vitamins were given and a continuous search was made for signs of infection. The liver function tests during this period (summarized in the table) did not significantly change except that the prothrombin concentration fell to 60 per cent of normal and the sulfobromophthalein retention became elevated twenty-four hours before death. About six hours before death pus was discovered in the urine, and subcutaneous sulfadiazine was given. Before this was done the patient seemed to rally and was able to talk. He began however to vomit repeatedly and to hiccup. During the night of the sixth postoperative day the patient suddenly vomited 1,000 cc. of dark guaiac positive material, aspirated a great deal of it and died twenty minutes later in respiratory distress. The clinical diagnosis of the immediate cause of death was rupture of an esophageal varix, brought about by the strain of repeated vomiting. The severe terminal episode may have been precipitated by the combination of depressed liver function as suggested by a decrease of the prothrombin concentration in spite of continuous administration of vitamin K and by bronchopneumonia which escaped clinical detection but was found at autopsy. The caloric intake of the patient in the postoperative period as charted in retrospect was too low and this with the administration of 1 grain (0.06 Gm.) of morphine in forty-eight hours may have been a precipitating factor.

‡ Twenty-four hours before death § Fifteen days after dental abscess.

Pathologic Examination.[8]—The following is a summary of the pathologic findings. The patient's brain has been sectioned serially and a subsequent communication will describe the details of the microscopic examination. The most conspicuous gross lesion in the sections was that illustrated in figure 2. The putamen of each lenticular nucleus was the site of multiple small cavities. Here nerve and glial cells had disappeared, leaving only scattered hypertrophied astrocytes. The globus pallidus on each side, the caudate nuclei and other structures appeared to be intact. Another lesion was found in the right middle frontal convolution, where large areas of the cerebral tissue showed evidence of softening. This was particularly pronounced in the convolutional white matter but also found in the cortex. In these regions the brain tissue had a gray, mottled appearance and the leptomeninges overlapping the softened zones were thickened. A section taken from this part of the brain showed a fairly complete necrosis of all nerve and glial cells in one convolution. These cells had disappeared, leaving only the proliferated endothelium of capillaries and veins and endothelial as well as microglial phagocytes. In adjacent convolutions the parenchymal damage was less severe. Although the architecture of the cortex was deranged, a fair number of nerve cells remained intact. Again the capillary endothelium had undergone hyperpla[illegible] were increased in number and showed [illegible] A fair number of large astrocytes could be seen. The only vascular changes were of the type commonly seen in reactions to necrosis. All blood vessels were patent.

The liver biopsy (six days before death) presented the same gross and microscopic appearance as did the liver at autopsy.

At autopsy the body was well developed and fairly well nourished and did not show obvious signs of chronic wasting disease. The only gross findings of significance were in the liver, lungs and gastrointestinal tract. The liver weighed 1,300 Gm. (a slight reduction in weight). The organ was considerably reduced in size, out of proportion to this slight reduction in weight. Externally the surface was diffusely and uniformly nodular with the individual nodules varying in diameter from 0 5 to 1 cm. (figs 2, 3 and 4). The color was in general a pale gray-brown with the depressed, fibrous scars standing out as paler gray or white strands of variable width. The organ cut with increased resistance to reveal a slightly more red cut surface in which the roughly spherical nodules were clearly demarcated. The fibrous trabeculae were of varying size and seemed to follow no uniform pattern. The gallbladder and bile ducts were all within normal limits. The same held true of the blood vessels. Although known to the pathologist, the site of the biopsy which had been taken six days before death could not be detected. The lungs weighed 800 and 580 Gm. on the right and left respectively (increased weight). The pleural surfaces were glistening, gray red, showing scattered subpleural 1 mm. petechial hemorrhages chiefly about the bases. On sections the lobes uniformly exuded copious amounts of serosanguineous fluid and showed similar petechial hemorrhages throughout the cut surface. The gastrointestinal tract was remarkable, as the stomach contained large amounts of red black semifluid material which gave a strongly positive guaiac reaction and was obviously changed blood. Examination of the esophagus and stomach failed to reveal either varix formation or ulceration, and the definite primary site of the hemorrhage could not be identified. (This unsatisfactory conclusion, as pathologists well know, is a not uncommon finding in cases of gastrointestinal hemorrhage.)

---

[8] Dr. S. L. Robbins made the pathologic description and Dr. R. D. Adams the neuropathologic studies.

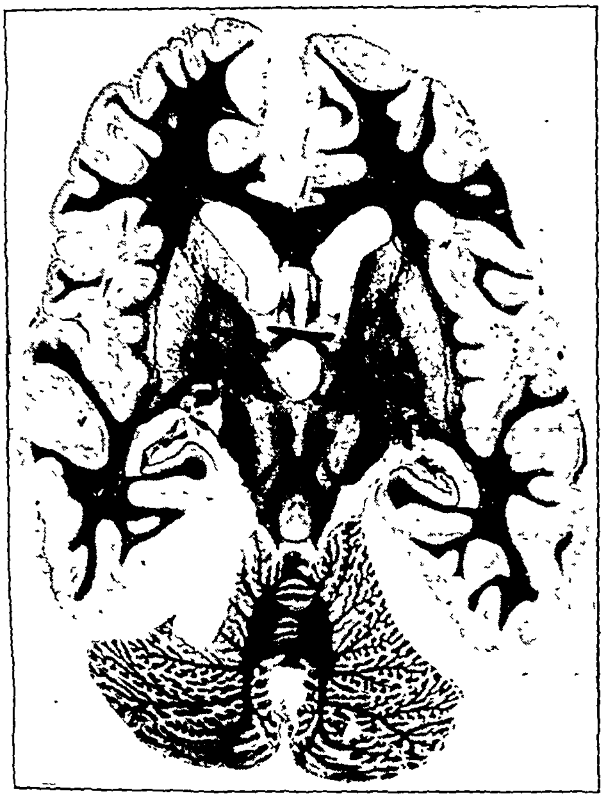

Fig. 2.—A section of the cerebrum cut in oblique plane approaching the horizontal. *Note* multiple small cavities in the outer segments of the lenticular nuclei. This cavitation is especially obvious when the lenticular nuclei are compared with the intact caudate nuclei. The globus pallidus on each side and other structures in subthalamus and midbrain are not altered grossly.

Microscopic examination showed the liver to be diffusely traversed by fibrous bands laid down in no apparent relation to the hepatic architecture, varying greatly in their width and cutting off nodules of liver parenchyma of variable size. In some cases the fibrous cords appeared to partition individual hepatic lobules, but in other areas the scarring appeared to involve many lobules. The fibrous bands assumed the width of a liver lobule in scattered areas and contained numerous proliferating bile ducts, scattered nests of viable liver cells and a moderate lymphocytic infiltration. There were widely scattered areas of apparent liver cell regeneration, but the great majority of the parenchymatous cells appeared to be fairly well preserved, conforming to the original architecture with no obvious signs of acute necrosis at present. The lungs, in addition to congestion and edema, presented early bronchopneumonia.

CASE 2.—J. R., a youth aged 18 years, Jewish, was the identical twin brother of the first patient. The initial symptoms began much earlier than in his brother but had remained comparatively mild. He had noticed some difficulty in handwriting ever since he first went to school at the age of 5 (fig. 6). There were also difficulties in other finely coordinated movements, such as holding a glass of water. The tremor was inconsistent and often imperceptible. It sometimes appeared at rest and was increased by a sustained motor activity such as squeezing one's hand. In March 1944 physical examination showed a corneal circumlimbar pigmentation similar to that seen in case 1. He also had bilateral pes cavus. His speech and gait were not remarkable. He had an inconstant, variable, rhythmic tremor of the hands greatly accentuated by sustained muscle tension. There was slight jerkiness in voluntary movements (fig. 6, handwriting). There were no pyramidal tract signs. The liver was within normal limits and the spleen was not palpable. There were no esophageal varices on roentgenologic examination. The patient refused to follow any dietary prescription and continued eating his regular diet, which con-

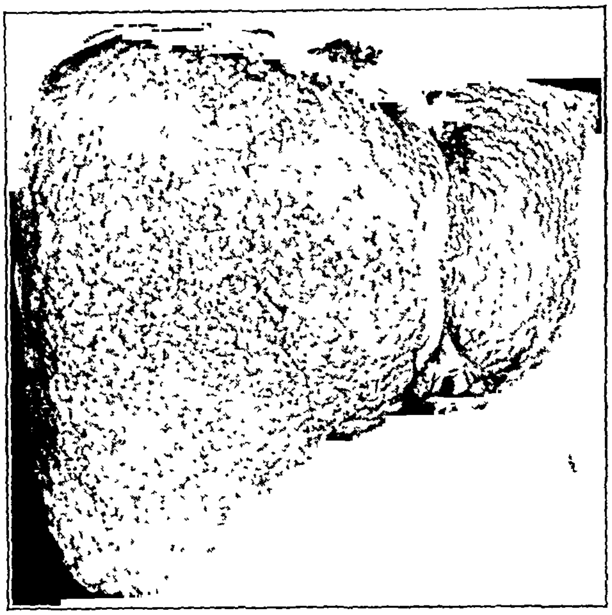

Fig. 3.—Gross appearance of the liver in case 1. External view of entire organ.

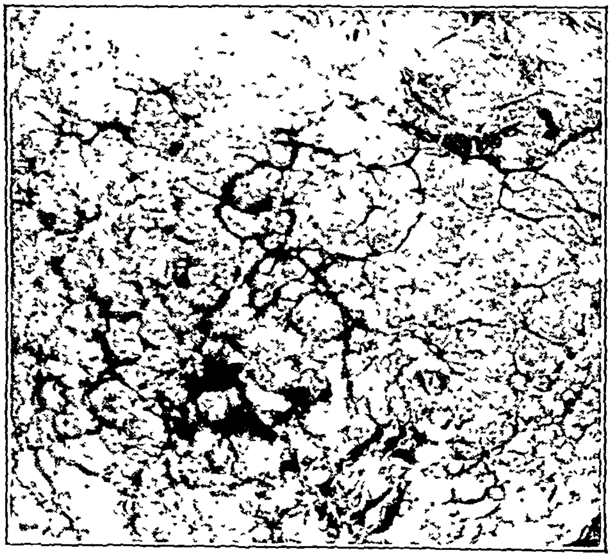

Fig. 4.—Close up of liver surface in case 1.

sisted of about 2,400 calories: carbohydrate 285 Gm., protein 111 Gm., fat 91 Gm.

Following the death of his twin brother the patient began to be concerned about his own condition and noticed a slowly progressive increase of his tremor, so much so that it became difficult for him to handle the copper plates in the printing shop where he worked.

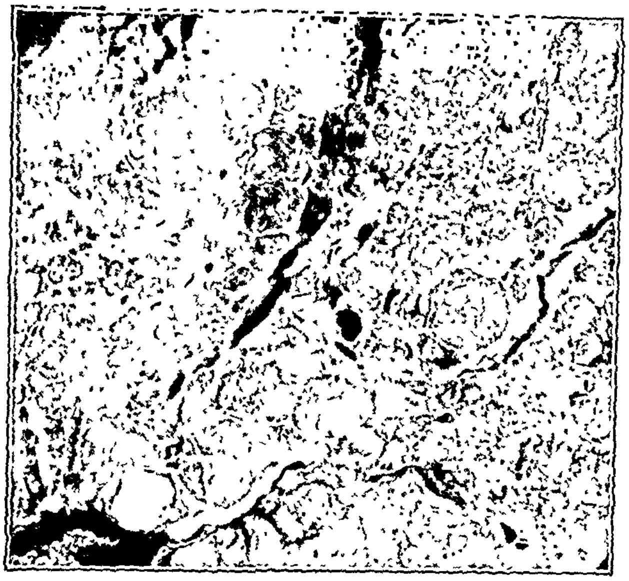

Fig. 5.—Cut section of liver in case 1.

In November 1944 his general condition was about the same except for a slight exacerbation of the tremor of the hands. The liver to percussion and palpation was somewhat smaller than previously, the edge being percussed 2 fingerbreadths above the costal margin in the right midclavicular line. The patient decided to start to take his diet regularly and, following a period of three weeks accompanied by some gastrointestinal difficulties, he succeeded in bringing his caloric intake to the desired level. His weight increased by 2 pounds (0.9 Kg.) in fifteen days. On January 25 he suffered from an infected tooth and had a temperature of 101 F. On extraction of the tooth and sulfadiazine therapy the infection subsided, but the patient remained anorexic and grew progressively weaker. During this time his food intake was definitely far below the desired level. On February 9 he was weak, irritable and pale. There was pronounced tremor of both hands even when at rest. Liver function tests are recorded in the table. It will be noticed that the cephalin flocculation was 3 plus and the prothrombin concentration 60 per cent. As the patient refused intravenous therapy, hourly feedings of carbohydrate and protein were begun in order to give him a daily caloric intake of about 4,000 calories. On February 12, after three days of ingesting 4,000 calories, the patient's mood was much improved and he had gained weight. Four days later he looked even better, stated that he felt hungry in spite of high caloric intake and his tremor was less noticeable. Liver function tests showed a prothrombin of 100 per cent and a 2 plus cephalin flocculation.

Fig. 6.—Samples of handwriting in case 2: I, in 1942; II, February 1944; III, October 1944; IV, November 1944.

Case 3.—*History.*—M. R., aged 19 years, sister of the identical twins (patients 1 and 2), was an art student. In the last two years she had given up fine pencil drawing because of "stiffness" (rigidity) of the fingers. When emotionally disturbed or excited she developed a fine, rhythmic tremor of the hands and arms. She was extremely apprehensive and sensitive. Her menses had ceased abruptly at the age of 16.

Examination.—She too had a Kayser-Fleischer ring identical with those seen in her brothers. There was bilateral pes cavus. She was highly myopic and had a wild, staring expression. At times a fleeting rhythmic tremor was noted in her arms, exaggerated by sustention, like squeezing one's hand. There were suggestions of cogwheel rigidity in the upper extremities. There were no pyramidal tract signs. Her handwriting (fig. 7), while better than that of the second patient, also revealed some difficulty in coordination. Her liver was small but within normal limits, and her spleen was not palpable. Laboratory data are given in the table.

Fig. 7.—Samples of handwriting in case 3: at top, when first seen in 1943; at bottom, February 1944.

In October 1944 the patient began to suffer from a dry hacking cough, running nose and mild sore throat. With this coryza she noticed three times blood streaked sputum. Shortly thereafter the patient started vomiting several times and refused food during one day. She was admitted to the hospital. On admission, physical examination was the same as in February except that her tremor was coarser and more constant and her motor restlessness more pronounced. There was great emotional instability, and tears appeared on little provocation. Sustained movement of any group of muscles exaggerated the tremor in the muscle group examined. The handwriting showed more signs of difficulty than had previously been noticed (fig. 9). X-rays of the chest and esophagus were negative. The blood streaked sputum was ascribed to congestion of the frontal sinuses, which on x-ray examination showed thickened lining. The patient refused all dietary measures and persisted in leading a rather erratic life. She is getting gradually worse with increasing tremor and emotional instability. The Kayser-Fleischer ring is growing wider; liver function tests, however, have not significantly changed.

CASE 4.—I. S., a man aged 38, Jewish, a shipping clerk, admitted to the hospital because of tremor of his hands of eight years' duration, had consulted many physicians in the past and had been demonstrated variously as a case of postencephalitic parkinsonism or of multiple sclerosis. The peculiarities of the neurologic symptoms together with the presence of a distinct Kayser-Fleischer ring led Dr. Denny-Brown to diagnose hepatolenticular degeneration. The patient first noticed the tremor eight years before, when he began to spill fluids from glasses. Later in the course of the first year he broke pencil points and his handwriting began to disintegrate (fig. 8). His symptoms reached a maximum intensity within one month and had persisted ever since with a slight worsening in the year before admission. For about five years there had been mild albuminuria, discovered incidentally during an examination for life insurance. Although the patient was intelligent and observant, he stated that he had not had any gastrointestinal upsets, whereas the patient's wife, a nurse who had known him for five years, was positive that he had numerous attacks of constipation, nausea and anorexia followed by abdominal distress and sometimes diarrhea. He had had a diet high in spiced and fatty foods, rather low in carbohydrates and probably adequate in protein.

Fig. 8.—Samples of handwriting in case 4: from top to bottom, 1931, 1938, 1944.

The parents of the patient were cousins once removed (fig. 10) and in another branch of the patient's family there had been marriage of cousins and mentally deficient male offspring in alternate generations. From the history of these relatives given by the patient it appears that infectious diseases or birth injury were unlikely factors. The uncertainty of the diagnosis, however, reduces the value of this observation. The patient has one half brother who is in good health. The patient had been working in a soap factory for a while, but the chemicals used there were not of the sort known to cause liver damage.

Physical examination revealed that the patient was thin, intelligent and cooperative. He did not appear to be in any distress. When he stood quietly and relaxed, no tremor was noticeable. The eyes showed a golden brown ring at the limbus of the cornea, and the fundus came into focus at 10 diopters. The liver was palpable about 2 fingerbreadths below the right costal margin in the midclavicular line. The spleen was found to be enlarged on percussion and was not palpable. X-ray studies of the chest, abdomen and esophagus were negative.

Fig. 9.—Samples of handwriting in case 3: at top, in 1943; at bottom, November 1944 at time of admission to the hospital.

The neurologic examination was negative except for the following findings: The patient's speech was somewhat blurred, slow and hesitant, with a nasal note. His tremor was not noticed as long as he stood quietly at rest. When he extended his arms before him the hands flapped at the wrist in gross rhythmic tremor. When the arms were flexed at the elbow and held before the patient the arm became involved with an involuntary gross movement in which the humerus rotated at the shoulder and the forearms flailed up and down. There was a coarse, arrhythmic intention tremor, but it was most pronounced at the point of completion of the intended action, so that on putting his finger on his nose the patient hit the object, but immediately the tremor threw his hand up to his forehead or down below his chin. Alternating movement of the fingers could be performed with the arms supported, but as soon as the arms were left unsupported fine movements were made impossible by the tremor. The patient was hospitalized for a short period for liver studies and was discharged on the 12th of July 1944 on a diet similar to that given to patient 1 but adjusted to a total of about 3,000 calories. He has taken it religiously ever since. It represented for him a great change in eating habits and at first was difficult to get used to. After two months the patient spontaneously reported an improvement in his general condition and a feeling of well being. He felt that his tremor had diminished to some extent. After three months he stated that for the first time

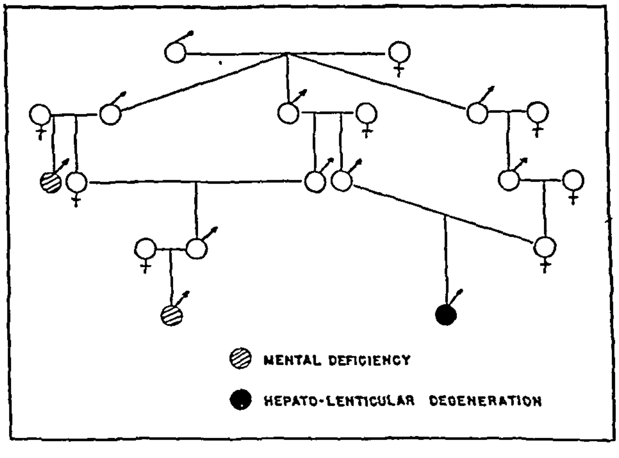

Fig. 10.—Intermarriages and occurrence of degenerative diseases in ancestry of patient 4.

in eight years he could manage to shave. Also for the first time since the onset of his symptoms he was able to fold garments which were manufactured at his place of work into the prescribed shape. The patient is intelligent and has a critical attitude toward the medical profession. Suggestion of improvement in this case seems unlikely. He and his family deny previous remissions. The laboratory studies of the case are reported in the table.

COMMENT

Neurologic Aspects.—The differential diagnosis of hepatolenticular degeneration is of special interest to neurologists. It is striking that many of the cases reported as such were undiagnosed initially and were confused with other conditions.

The diagnosis of hepatolenticular degeneration should be considered in every case of tremor or postural disorder in a young person. The pigmented circumlimbar corneal ring of a golden color is seen in hepatolenticular degeneration and may be considered pathognomonic. Several cases with absence of the Kayser-Fleischer ring have been reported in the literature, and in some instances special measures were necessary to visualize the ring.[9] In most of these cases no postmortem examination had been done, so that the diagnoses remain unproved. On the other hand Hall [2] found the corneal pigmentation present in 20 of 25 proved cases, and unless cirrhosis of the liver can be demonstrated the pigmentation remains the one certain positive clinical sign. Although the presence of the ring is pathognomonic, its absence does not conclusively rule out hepatolenticular degeneration. As Wilson [7] has stressed, the diagnosis should depend on the neurologic evidence of lenticular disease.

The rhythmic tremor, which may be present in repose but not in full relaxation, is brought out or exaggerated by sustained muscular tension rather than by movement. In addition there may be any or all of the other signs of disease of the basal ganglions, chorea, athetosis, dystonia. There are often striking emotional disturbances which may misdirect an examiner toward purely psychiatric considerations.

The most common error in diagnosis is that of mistaking these cases for postencephalitic parkinsonism. This is not surprising, as there are many points of similarity. The rhythmic tremor is qualitatively similar and may be indistinguishable. Emotional disturbances are common in both, but outright oddities of behavior are not a usual part of hepatolenticular degeneration. The plastic rigidity may be identical. The posture of parkinsonism may be seen in Wilson's disease. The resting or latent tremor of hepatolenticular degeneration is exaggerated by motion and sustention while the tremor of parkinsonism is decreased by activity and effort. In general the tremor of parkinsonism is more prominent in the fingers than in the wrist. The signs of postencephalitic parkinsonism develop rapidly and then remain stationary, whereas those of hepatolenticular degeneration are more often progressive. In both disorders there is rarely any pyramidal tract involvement. In some of Wilson's cases the destruction of the lenticular nucleus was so extensive as to impinge on the internal capsule and produce some pyramidal tract signs. The differentiation of postencephalitic parkinsonism and hepatolenticular degeneration may present extreme difficulties.

The disease may be differentiated from choreoathetosis by the fact that the latter disorder is usually associated with hemiplegia and rarely with a parkinsonian tremor. Multiple sclerosis is distinguished chiefly by evidences of remission and asymmetry of signs. In cases in which these features are absent, when optic atrophy is lacking, the peculiar flapping tremor at the wrists and the corneal pigmentation form the chief differentiating characteristics. The possibility of pseudobulbar palsy may be suggested by dysarthria and difficulty in swallowing. However, the presence of pyramidal tract signs and absence of tremor of the extremities are unusual and are against hepatolenticular degeneration. Some cases have been misdiagnosed catatonic schizophrenia and were not recognized until autopsy. It would appear from the foregoing that the signs of organic disease should exclude any consideration of purely functional disorders. Yet many cases, including case 1 in this paper, have been erroneously diagnosed as psychoneurosis.

In general, differential diagnosis of hepatolenticular degeneration is not difficult if it is kept in mind whenever one encounters a case of tremor or postural disorder in a youth. The clinical diagnosis must be based on the neurologic features because there is seldom clinical or laboratory evidence of distinctive liver disease. Direct visualization and biopsy of the liver, as in one of our cases, is conclusive. In this case, however, it proved to be a dangerous procedure.

Medical and Biologic Aspects (comments and interpretation of laboratory studies).—The presence in hepatolenticular degeneration of cirrhosis of the liver at autopsy is a constant feature. The extent of the hepatic lesions found at postmortem usually is far more impressive than would have been anticipated from the symptoms. Liver function tests usually fail to show hepatic dysfunction in spite of the advanced anatomic changes (Walsh,[10] Lüthy,[11] Barnes and Hurst [12]). Sweet, Gray and Allen [13] showed that some of the modern liver function tests are sensitive enough to demonstrate hepatic damage in these cases in the absence of hepatic symptoms. They have also reviewed the evidence that hepatic damage precedes the neurologic manifestations.

The value in hepatolenticular degeneration of the routine procedures used for the demonstration of liver disease was investigated. Sweet, Gray and Allen had found the serum colloidal gold test to be the most sensitive reaction. In our hands this test was reliable in a series of cases of cirrhosis of the liver and acute hepatitis. It was found, however, negative in cases of hepatolenticular degeneration. It should be noted that the diagnosis of some of the cases of Sweet, Gray and Allen was by no means conclusive and that the colloidal gold solutions used in this hospital are prepared according to Merritt and Fremont-Smith [14] in a way slightly different from that indicated by Gray.[15] For these reasons it seems impossible to draw any conclusions from these contradictory results in a small group of cases.

The liver function tests (recorded in the table) were done by the surgical research laboratory of the hospital and the technics used were those described by Quick[16] for the prothrombin time, White, Deutsch and Maddock[17] for the sulfobromophthalein excretion test, Quick[18] for the hippuric acid synthesis test and Hanger[19] for the cephalin flocculation test. Intravenous glucose tolerance tests were performed according to the technic of Lozner and his associates,[20] and other laboratory methods used were those described by Peters and Van Slyke.[21]

The glucose tolerance tests were repeatedly normal in all of the cases. Of all the liver function tests the cephalin flocculation test alone either varied along with the changes in the patient's condition (cases 2 and 3) or remained consistently positive, thus indicating liver disease which was undoubtedly present. The remaining liver function tests showed either normal values, insignificant deviations from the normal or inconsistent changes. This picture of liver function tests was especially striking in case 1, in which at the time of liver biopsy which revealed extensive anatomic damage (figs. 2, 3 and 4), none of the tests, except the cephalin flocculation, indicated any damage. This shows that liver disturbance in this disease may be present and developed to a high degree and still may remain unrecognized. Thus one argument of those who think the neurologic disturbance to be the primary factor because no liver damage is sometimes evident prior to the appearance of neurologic signs loses its value. The terminal changes of the liver function tests in case 1 and their behavior during an infectious episode in case 2 are presumptive evidence that the liver disorder in this disease varies in intensity and is subject to exacerbations in times of functional stress. In the literature no member of a family suffering from the disease has developed nervous lesions at a time when cirrhosis has been definitely proved to be absent, whereas there are a number of cases on record in which one sibling has been found to have cirrhosis without nervous lesions.

Experimental evidence points to the liver as the organ primarily involved and perhaps responsible for the lesions of the central nervous system. Although Graef, Negrin and Page[22] have observed cirrhosis of the liver following the causation of hypothalamic lesions, they argue that the mechanism may be an indirect one through changes of feeding habit. Whether this may apply to patients with Wilson's disease remains doubtful. The work of Kallo and Oberling,[23] who have produced liver changes through lesions to the lenticular nuclei, has never been repeated and their evidence is not conclusive. On the other hand, Mahaim[24] produced central nervous lesions in dogs by causing severe hepatic damage by the injection of 50 per cent alcohol into the biliary tract. The cerebral lesions were observed thirty to eighty days following the causation of the hepatic damage and were "intense lesions of the nerve cells with slight predominance for the cortex and particular vascular and neurological lesions in the central nuclei of the thalamus and the caudate nucleus" (translated). Kirschbaum[25] obtained similar lesions in the brain of one dog which survived ligation of the hepatic artery for ninety days. Crandall and Weil[26] demonstrated in vitro a substance in the serum of dogs with experimental hepatic lesions that was causing damage to the myelin sheaths of rats' spinal cords when these were incubated for twenty-four hours at 37 C. in such serums. The serum of the same dog was inactive in this respect prior to liver lesions. We were unable to obtain any clearcut results when spinal cords of rats were incubated in the serum of our patients. Pathologic evidence shows that liver disease can cause brain lesions (Scherer,[27] Schaltenbrand[28]) and in hepatolenticular degeneration the clinical impression[13] points in the same direction.

The few facts known about the pathogenesis of hepatolenticular degeneration suggest the liver as one important factor. Observation of our patients showed that exacerbations followed or were accompanied by periods of low food intake and gastrointestinal distress. On the other hand all remissions observed followed periods of high food intake. These facts lead to the use in these patients of high caloric diets low in fat (4,000 calories, 3,000 derived from carbohydrate, 600 from protein and 400 at the most from fat). Such diets have recently been given in this disease by Wollaeger and Shands,[29] but these authors report no observations on the effects of this treatment in their patients, Dimitz and Vujić[30] had reported some success in 1925 from a high caloric, meatless diet. Obviously the effects of such dietary measures in a chronic neurologic disease are hard to evaluate and, as liver function tests sometimes vary even in untreated patients, they are of little help. Furthermore, one cannot expect a reversal of clinical symptoms due to irreparable anatomic damage of the central nervous system. Final evaluation of any therapy is possible only after a period exceeding the average life expectancy of such patients, and some presumptive evidence could be gained if a previously slowly progressive course could be arrested for a period lasting longer than any previous remission. Detailed metabolic studies which are in progress also might bring a better knowledge of the nutritional aspects of the disease. In the 3 treated patients of this series who were under observation for two, six and ten months respectively while taking diets, as described, clinical observation alone (in the absence of any measurable data) suggested that they all got somewhat better and that their neurologic disturbances became stationary and certainly in 1 case (4) improved somewhat. The dietary measures appeared to be of help in shortening setbacks associated with minor infections.

CONCLUSIONS AND SUMMARY

1. Four cases of hepatolenticular degeneration (1 with biopsy of the liver and autopsy, 2 in siblings of this patient) had all been previously misdiagnosed as either parkinsonism, psychoneurosis or multiple sclerosis.

2. Laboratory studies disclosed that the cephalin flocculation test alone of all liver function tests performed was positive in the majority of cases, whereas the hippuric acid synthesis, sulfobromophthalein excretion and the prothrombin time were often not significantly altered even in the presence of pronounced anatomic liver changes. Positive liver function tests in periods of functional stress indicated the capricious type of liver disease, with periods of detectable impairment of function alternating with periods of functional adequacy.

3. In these cases, where exacerbations were related to periods of inadequate diet, remissions followed periods during which the patients had been taking high caloric diets relatively low in fat. In 1 patient the first remission in eight years occurred after institution of such a diet.

MALARIA THERAPY IN SYPHILITIC PRIMARY OPTIC ATROPHY

WALTER L. BRUETSCH, M.D.
Indianapolis

Malaria therapy, according to Moore and Woods,[1] is the most efficacious method of treatment of primary syphilitic optic atrophy. This therapeutic study of the Johns Hopkins group, done with the greatest accuracy and comprising 250 patients, has no equal in the literature. Others[2] observed similar gratifying results with the use of malarial fever.

In the opinion of Kierland and O'Leary[3] malaria treatment is also superior to Swift-Ellis therapy in the control of failing vision due to syphilis. The abandonment of intraspinal therapy is advocated because of its tendency to extinguish vision suddenly in 10 per cent of patients so treated.[4]

There are no comparable large and well studied groups of patients with syphilitic optic atrophy who were treated with artificial fever. In the small series of patients who were subjected to hyperpyrexia by Menagh[5] and Neymann[6] the percentage of visual improvement appears to be lower than in the malaria treated patients with optic atrophy.

PATHOGENESIS OF PRIMARY SYPHILITIC OPTIC ATROPHY

It is difficult to understand, at first sight, why malaria therapy should be useful in syphilitic optic atrophy, which has generally been looked on as a degenerative process. In the past there have been many misconceptions as to this condition, first of all, that syphilitic optic atrophy is just another variety of the tabetic process. This idea had early led to the designation of "tabetic optic atrophy," a term which should be discarded in favor of "primary syphilitic optic atrophy." To the clinician it has been a long established fact that so-called tabetic optic atrophy is not confined to tabetic patients but occurs not infrequently in dementia paralytica, in meningovascular syphilis and even in syphilitic persons who never had and never will develop any sign of tabes.

Moore and Woods[4] made the important observation that there is no significant difference in the prognosis of treated or untreated optic atrophy, whether this condition is associated with any of the three main types of neurosyphilis or whether it occurs as an isolated symptom in an individual with syphilis. From the clinical facts only they concluded that there is probably also no difference as to the pathology and the pathogenesis. In this conclusion I concur after having examined microscopically in the past fifteen years the visual pathways of 70 patients with all types of syphilis of the central nervous system. Of these, 10 had complete syphilitic optic atrophy and 2 had unilateral optic atrophy. Others had optic nerve changes ranging from the earliest lesion to far advanced atrophy but still leaving the patient with some useful vision. In another group the optic nerves were normal.

From the study of this large anatomic material it became apparent that primary syphilitic optic atrophy is due to a chronic inflammatory process followed by degeneration of the nerve fibers. Infiltrations, composed of lymphocytes and plasma cells, extend from the periphery along the septums toward the interior, producing first marginal degeneration of the optic nerves. On the perimeter this manifests itself in a concentric and slowly advancing narrowing of the visual fields. In other instances of optic atrophy the entire diameter or large irregular sectors of the optic nerves become involved at once by the inflammatory process. The principal site of the exudative features is in the intracranial portion of the optic nerves or in the chiasm or both and is dependent on a varying degree of syphilitic basilar meningitis. From here the atrophy of the visual nerve fibers proceeds in both directions. The essential lesion in the interior of the optic nerves and chiasm consists of cellular infiltrations in the septal connective tissue and around the blood vessels (fig. 1). Only if there is an extensive exudative process at one time or another in the interior of the nerves will optic atrophy occur. A few scattered lymphocytes and plasma cells within the visual pathways, while not completely harmless, will not cause large scale degeneration of the nerve fibers. In addition there is round cell infiltration in the pia of the intracranial optic nerves and chiasm (fig. 2). The latter, it should be emphasized, may be present without atrophy of the optic nerves.

The pathologic basis of syphilitic optic atrophy, therefore, is more like the process of dementia paralytica than of tabes. This knowledge is not new. Previous investigators made the same observation. In other words, my own findings uphold the anatomic studies

of Léri,[7] Stargardt[8] and Richter[9] that the primary lesion in syphilitic atrophy of the optic nerves is a peripheral and interstitial neuritis, which is followed by a slow secondary degeneration of the nerve fibers. Many writers on this subject have been so fascinated by the term tabetic optic atrophy that they have overlooked this important conclusion of the earlier workers, or they have become confused by the many different opinions which have been expressed on the pathogenesis of optic atrophy.

MECHANISM OF MALARIAL THERAPY IN THE ARREST OF SYPHILITIC OPTIC ATROPHY

After having gained a more accurate insight into the pathogenesis of syphilitic optic atrophy, it is easier for one to understand the beneficial action of malaria treatment. One of the more important effects of malaria therapy consists in arresting the inflammatory phase of the neurosyphilitic process. It is not yet known in exactly what manner this is brought about. There is evidence that the activation of the mesodermal tissue, which is produced by the malaria plasmodia and not by the elevated temperature, is responsible for the cessation of the inflammatory reaction.[10]

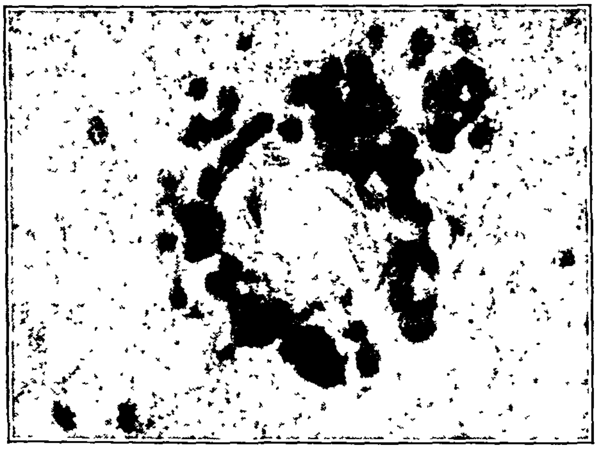

Fig. 1.—Perivascular infiltration of vessel in interior of optic chiasm in syphilitic primary optic atrophy. Toluidin blue stain.

The exudative phenomena have usually been interpreted as the direct effect of Treponema pallidum. Therefore, it was argued, if temperatures above normal destroy the spirochetes, the round cell infiltrations will recede. For practical purposes it has been shown, however, that hyperpyrexia which can be produced with safety in man is not deleterious to the syphilitic organism.[11]

In this connection the question arises: What is the relation of T. pallidum to optic atrophy? Igersheimer[12] made special studies concerning this problem. He observed an occasional spirochete in the meninges of the atrophied nerves in one third of the cases. On account of the scarcity of spirochetes, Igersheimer felt that treponemes are not directly responsible for the degeneration of the optic nerves. In my own material not a single treponeme was observed in the optic nerves, although in 1 instance masses of treponemes were present in the cortex of an orbital convolution immediately opposite the atrophied nerves. Spirochete studies in other types of neurosyphilis also tend to show that the pathologic process is only indirectly the result of T. pallidum. At the present stage of knowledge the exact relationship of the treponemes to the microscopic changes in the pathogenesis of the various types of neurosyphilis is not definitely known. Varied stages of tissue immunity obviously play an important role.

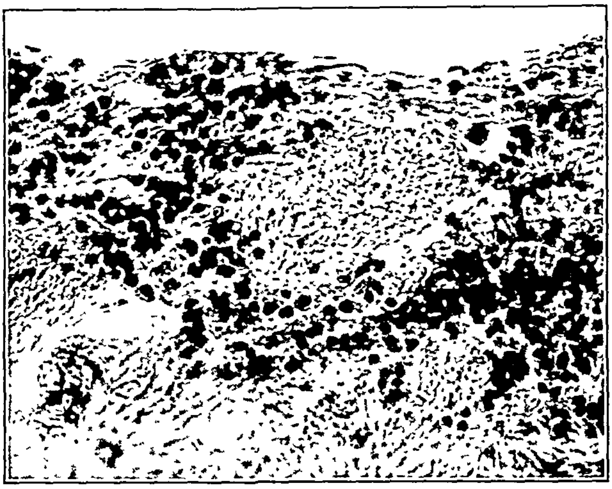

Fig. 2.—Round cell infiltration in pia of optic nerve, penetrating along the septums toward the interior in syphilitic primary optic atrophy. Hematoxylin-eosin stain.

Malaria therapy, besides changing the tissue immunity, inhibits the inflammatory element of syphilitic optic atrophy, and the secondary degeneration of the nerve fibers ceases. Since most frequently the inflammatory process advances from the periphery toward the interior, enough normal tissue of the central portion of the nerve is left for useful vision (fig. 3).

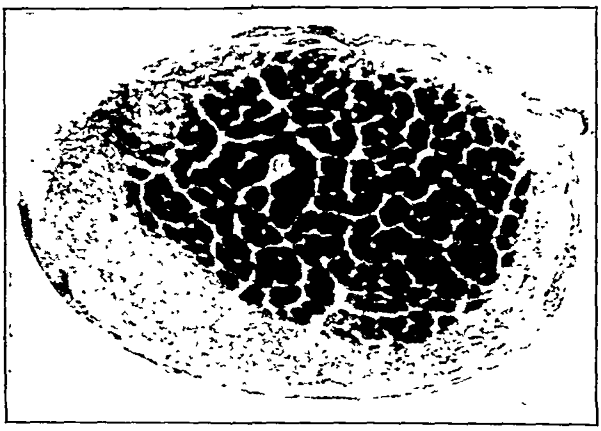

Fig. 3.—Beginning syphilitic optic atrophy, arrested by malaria therapy. The optic nerve shows a large marginal area of degeneration. Following malaria treatment the irregular contraction of the visual field ceased to progress. Myelin sheath stain.

Unfortunately, in a number of patients optic atrophy progresses in spite of malaria therapy. For some unknown reason malaria is ineffective. The inflammatory feature continues unabated, and complete optic atrophy ensues. Or malaria therapy arrests the exudative process, but the resorption of the round cell infiltrations is so slow that degeneration of the nerve fibers is almost complete before all the inflammatory cells have been removed. If one has the opportunity to examine the optic nerves of patients with syphilitic optic atrophy who have been treated with malaria, one will find that the absorption of the plasma cells and lymphocytes is a matter of years rather than of months. This fact expresses itself in the therapeutic results. For three years following malaria therapy slow progression of failure of vision may continue. Thereafter, no additional loss of vision has been noted.[4] On the other hand, in the patients who react most favorably to malaria treatment the concentric constriction of the visual fields will gradually expand, evidencing a capacity for recovery of partially damaged nerve fibers.

CAN THE TREATMENT OF SYPHILITIC OPTIC ATROPHY BE IMPROVED?

It is quite evident, then, that treatment of syphilitic optic atrophy depends on the arrest of the chronic inflammation within the optic nerves. On this principle rests, to a large degree, the effectiveness of malaria therapy. In favorable cases one course of malaria will suffice. If visual failure continues to progress, one should contemplate another course of malaria. Quartan malaria (*Plasmodium malariae*) will have to be used, since in the interim an immunity has developed to the tertian strain with which the patient was previously inoculated.

Penicillin has been shown to reduce in neurosyphilis the increased cell count of the spinal fluid. To follow up malaria with penicillin or give it concomitantly may be a worthwhile procedure by enhancing the anti-inflammatory action of malaria therapy. To rely on penicillin alone would be hazardous. In my experience penicillin does not come up to the efficacy of malaria in the treatment of dementia paralytica, and the same may be true in its use in syphilitic optic atrophy.

SURGICAL INTERVENTION FOR SYPHILITIC OPTIC ATROPHY

In recent years syphilitic arachnoiditis involving the optic nerves has been held responsible for optic atrophy, and surgical intervention has been recommended.[13] Throughout this study especial attention was given to this conception. In every instance the chiasmatic region was carefully examined at necropsy. The base of the brain with the optic nerves and with the arachnoid in position was embedded for microscopic examination. From the histologic investigation the impression was gained that optochiasmatic arachnoiditis may be responsible in an exceptional case for the atrophy of the optic nerves. In by far the largest majority of primary syphilitic optic atrophy the arachnoidal adhesions about the optic nerves and chiasm are not the cause of the degeneration of the optic nerves. In some instances of syphilitic optic atrophy there is no adhesive arachnoiditis whatever in the optochiasmatic region. In others the thickened arachnoid passes harmlessly over the optic nerves. If in such cases the fibrosed and infiltrated arachnoid is surgically removed, there still remains within the optic nerves the inflammatory process, which is the essential factor in producing degeneration of the visual nerve fibers.

CONCLUSIONS

The good results with malaria therapy in the control of syphilitic optic atrophy can best be explained on the basis that the degeneration of the optic nerves is due to an inflammatory process, which is arrested by malaria treatment.

A patient with failing vision due to syphilitic primary optic atrophy should at once receive malaria therapy.

Routine antisyphilitic treatment with trivalent arsphenamine, bismuth and mercury is entirely inefficacious in syphilitic optic atrophy, and the patient will become blind almost as rapidly as if he had received no treatment at all.

ABSTRACT OF DISCUSSION

Udo J. Wile, Medical Director (R), U. S. Public Health Service: Among all of the late sequelae of acquired neurosyphilis, cases of primary optic atrophy have been, from the standpoint of therapy, the most hopeless group. Prolonged treatment with arsenicals, heavy metal and iodides fail to elicit any therapeutic response on the progressive changes of the optic nerve which ultimately lead to complete amaurosis. I am in accordance with Dr. Bruetsch's statement that, following the use of malaria, many cases have responded by a definite slowing up of the process, and a few have established a status quo which permitted the patient to sustain a limited vision indefinitely. In the absence of definite foci of spirochetes, such beneficial changes could be due only either to the relief of pressure, if this was present, or by the resolution or arrest of an inflammatory process as outlined by Dr. Bruetsch. Similar results, probably explainable on the same basis, occur with the not infrequent relief of root pains in tabes. Here again we are dealing not with the presence of organisms but with an inflammatory condition of the posterior roots and ganglions, which seems to be relieved not only by bouts of fever induced by malaria but also by mechanically induced pyrexia. My experiences convince me that thus far fever therapy, and particularly malaria, offers the only hope for arresting or delaying the process of optic atrophy. The mechanism of this therapy is adequately explained by Dr. Bruetsch's theory that the degeneration is caused by an inflammatory process.

Dr. Alan C. Woods, Baltimore: I agree with the author that optic atrophy is not limited to tabes. However, it is still true that the majority of patients with syphilitic optic atrophy also have tabes, which certainly indicates some close link in the pathogenesis of the two. I also agree that inflammatory reactions are responsible for the degeneration of the optic nerves. However, since in syphilis the inflammatory process is the response to an infectious agent, there is no reason to suggest that "the pathologic process is only indirectly the result of Treponema pallidum." The failure to find spirochetes in the optic nerve does not preclude their presence. Even in dementia paralytica, in which their presence is accepted beyond doubt, investigators as careful as Jahnel, for example, do not always find spirochetes in the brain. In my experience, fever treatment with malaria or with artificial hyperpyrexia has produced changes in the spinal fluid indicating an abatement of the inflammatory processes as evidenced by a drop in cell count and total protein. We therefore can rightfully assume that fever is largely responsible for the therapeutic success. Our present methods of treating central nervous system syphilis thus far have never given 100 per cent results. In some of the cases of failure the therapeutic method itself must be held responsible. In other cases the tempo and extent of the disease process are such that our present methods of treatment are totally inadequate. Therefore, in rapidly progressing failure of vision, just as in rapidly progressing dementia paralytica, the chances of arrest are poor, and when the entire optic nerve is involved the prospect of preservation of useful vision with the weapons at hand is also poor. One must also realize that the progression of tissue change once initiated by inflammatory reactions may continue because of various secondary forces. It is still too early, I feel, to conclude that fever produced by malaria or other methods, alone or combined with penicillin, is superior to penicillin as the single therapeutic agent when penicillin is given in optimum time-quantity dosages. The author is to be complimented for his provocative thinking on the question of the pathogenesis of neurosyphilitic processes.

F.: Surgical Treatment of Syphilitic Optic Atrophy (Syphilitic Optico-Chiasmatic Arachnoiditis), Dis. Eye, Ear, Nose & Throat **1**: 326, 1941. Bruetsch, W. L.: The Mechanism of Malaria Therapy in the Arrest of Syphilitic Primary Optic Atrophy.

Dr. J. E. Moore, Baltimore: It is urgently to be desired that the pathologic study of syphilitic primary optic atrophy, which Dr. Bruetsch has here presented in brief summary, be subsequently published in expanded form. The student of the subject desires much greater documentation, with correlation of clinical data, treatment administered and pathologic findings. Especially gratifying to the clinician is Bruetsch's concurrence in the favorable effect of malaria in arresting the progress of the atrophic process, and his insistence on the immediate necessity for this form of treatment as soon as the diagnosis is established. Likewise important, in view of the recent fad for surgical intervention in this country and abroad, is the author's demonstration that, in the majority of cases of syphilitic primary optic atrophy, adhesive optochiasmatic arachnoiditis plays no part in the development or progress of the atrophy. From the clinical point of view it is difficult to agree completely with the author's concept of the pathogenesis of optic atrophy and his statement that its pathologic basis is more like that of dementia paralytica than of tabes. As observed clinically, primary optic atrophy is actually far more frequent in tabes than in any other form of neurosyphilis. In dementia paralytica, optic atrophy rarely occurs except when tabes is associated, and the entire disease process is properly designated taboparesis. In tabes itself, it is an old and frequently confirmed observation that optic atrophy is often the first manifestation, occurring years before the development of obvious damage to the posterior roots and columns of the spinal cord. These facts and others have led many observers, including myself, to the hypothesis that the pathogenesis of syphilitic primary optic atrophy is identical with the pathogenesis of tabes dorsalis itself. The latter is as yet unknown. Tabes differs from all other forms of neurosyphilis in many extraordinary respects, among which are the extreme selectivity of the neurologic damage, the absence of treponemes in the nervous system (here pointed out by Bruetsch himself for the optic nerves), the low reagin content of blood and spinal fluid, and the refractoriness of the disease to treatment. A tabes-like disease, with degeneration of the posterior roots and columns of the spinal cord, of the peripheral nerves, and with primary optic atrophy, has been produced in experimental animals by prolonged maintenance on a diet deficient in certain components of vitamin B. Is it possible that the reason some neurosyphilitic patients develop tabes with or without optic atrophy, or the latter alone, is a combination of the influence of syphilis with some other factor not as yet defined, possibly dietary deficiency? The answer to this fascinating question is likely to be had, if at all, neither from clinical nor from pathologic observations on neurosyphilitic patients but instead from carefully planned experimentation.

Dr. Bernhard Dattner, New York: I am completely in accord with Dr. Bruetsch's chief point, that malaria therapy is the indicated treatment in syphilitic primary optic atrophy and that in terms of the final visual result it is definitely superior to either intraspinal therapy or to routine antisyphilitic treatment with trivalent arsenicals and heavy metals. I am likewise in agreement with Dr. Bruetsch that the atrophic process in the nerves usually begins in the intracranial portion of the nerve and is characterized by thickening and perivascular round cell infiltrations of the overlying pia and its intraseptal prolongations in the nerve. The degeneration occurs first usually in the marginal fibers, often involves nerve bundles and may also involve the central papillomacular bundle. However, I am not convinced that the primary degeneration of the optic nerves, which in my experience is seen predominatingly in association with tabes and taboparesis, is paralytica, is entirely secondary to preceding inflammatory changes either in the pial septums or around the blood vessels. The large mass of anatomic material assembled by Dr. Bruetsch is impressive, and one awaits with interest a detailed report on the point emphasized by Dr. Bruetsch, namely that the degenerative process in the nerve is always secondary to an extensive preceding exudative process. If this point can be established it will go a long way to clearing up the enigma of primary syphilitic optic atrophy. If one grants Dr. Bruetsch's hypothesis of the pathogenesis of primary syphilitic optic atrophy, his conclusion that the mechanism of malarial therapy is an arrest of the neurosyphilitic inflammatory process is quite logical. Indeed, in a way the conclusion supports the original hypothesis. Ophthalmologists have for years employed the nonspecific protein reaction in the treatment of ocular inflammation and have amassed a considerable volume of evidence to indicate its value. However, the nonspecific protein reaction is a complex affair including not only the febrile reaction and leukocytosis but a general stimulation of the reticuloendothelial system, changes in the permeability of the capillaries, alterations in the colloidal contents and stability of the serum with changes in the sedimentation rate, immunologic changes with a mobilization of preformed antibodies and tissue desensitization, and various other changes. While there is a widespread belief that the beneficial clinical changes which follow the reaction are largely proportional to the degree of fever and leukocytosis which accompany it, this is far from being universally accepted, and many observers believe that equal, if not superior, results are obtained with mild proteins which cause little fever or leukocytosis. They attribute the favorable results to other phases of the nonspecific protein reaction. Dr. Bruetsch takes the latter view and cites in its support his 1932 work, which demonstrated that malarial therapy produced a reaction in the reticuloendothelial system, with stimulation of the capillary endothelium, the histiocytes and undifferentiated mesenchyme cells. This makes a logical argument, and considerable sound experimental work may be cited to support this view. The argument is predicated, however, on the premise that the degeneration in the optic nerves is secondary to a preceding inflammatory reaction. The evidence on this point is not yet entirely convincing. The theory that the degeneration in the optic nerves and posterior columns is secondary to a combination of neurosyphilis and vitamin deficiency is likewise bolstered by sound experimental work. I do not think it can as yet be discarded in favor of the evidence here presented. I am in full accord with Dr. Bruetsch on his views on opticochiasmoarachnoiditis.

Dr. Walter L. Bruetsch, Indianapolis: The discussers are in accord that malaria therapy is the most efficacious method of treatment of syphilitic primary optic atrophy. As to the degree of efficacy of penicillin alone, no definite statements can be made. The audience has been somewhat astounded by my statement that the pathologic basis of so-called tabetic optic atrophy is more like that of dementia paralytica than of tabes. In the past forty years only five anatomic studies have been made which consisted of sufficient material to be of conclusive value (Léri 1904, Stargardt 1913, Richter 1921, Igersheimer 1926, Behr 1917-1938). Every one of these investigators, with the exception of Behr, agrees that there is an inflammatory process in syphilitic primary optic atrophy and that the pathologic changes in the optic nerves are the same whether the optic atrophy occurs in tabes or in dementia paralytica. They are also the same in meningovascular syphilis. Optic atrophy occurs more frequently in tabes. The pathogenesis of syphilitic optic atrophy is linked up with the pathogenesis of tabes dorsalis. However, an expert on the histopathology of tabes such as Richter disclaims any semblance of the histopathology of tabetic optic atrophy to the process in the cord in tabes. Syphilitic primary optic atrophy, particularly the early and intermediate stage, is by no means rare in cases of dementia paralytica without tabetic cord involvement. The reason why in dementia paralytica optic atrophy has not been observed more often clinically is the fact that in the era before the advent of malaria therapy dementia paralytica, in contrast to tabes, was a fatal disease within an average of one to three years. Later the same therapy, namely malaria, which reversed the inflammatory process in the paretic brain cortex, also arrested the exudative process in the optic nerves, which in the early stage is limited to the marginal zone. The marginal degeneration of syphilitic optic atrophy has usually extended far into the interior of the optic nerves before the patient becomes aware of failing vision and consults a physician. At that time the process in the optic nerves has already existed for several years. For this very reason every syphilitic individual with a positive spinal fluid should have a visual field examination once a year. If a narrowing of the visual fields is present although the optic disks may still be normal, a diagnosis of beginning syphilitic optic atrophy is justified, and malaria therapy enforced by penicillin should be instituted. There is no conclusive evidence that vitamin deficiency plays any role in the production of syphilitic primary optic atrophy. The experimental work to which Dr. Moore referred is far from being convincing, and in human neuropathology nothing is known that even in extreme cases of the vitamin deficiency diseases the optic nerves become involved. It would be unfortunate if, on account of this suggestion, attempts should be made to treat syphilitic optic atrophy with vitamin pills.

SHIGA DYSENTERY

MAJOR LUCIAN A. SMITH
Medical Corps, Army of the United States

In New Guinea, as in other parts of the world, bacillary dysentery, or shiga dysentery, will always be an important problem. It is particularly important to the armed forces because it renders fighting men noneffective and it increases the burden of the Medical Corps. Because of the necessity for keeping units of the armed forces as close to full effective strength as is feasible, it is desirable to utilize every means of arriving at the diagnosis as early as possible in order to shorten the period of hospitalization and to return such patients to duty.

By formal definition bacillary dysentery, or shiga dysentery, is an acute infectious disease of the lower bowel caused by the Shigella group of organisms and manifested by fever, cramps, nausea, vomiting and frequent stools containing mucus, pus and blood. Often the arbitrary statement is made that the stools of bacillary dysentery may be distinguished by the presence of pus, blood and mucus, that those of amebic dysentery contain only blood and mucus, and that the stools of simple diarrhea contain only mucus. Such a statement is correct in well developed cases but may be misleading in the earliest phase of the disease, the phase in which the certainty of diagnosis is most important.

All too often there is a tendency among soldiers to ignore various types of diarrhea or dysentery until their symptoms become severe. Anything less severe may be dismissed under the common designation "the G. I.'s," and the soldier may place the blame on the cleansing soap, on dirt on the mess gear or even on the chlorine in the water.

DIAGNOSIS

The medical officer who sees the patient first may not have adequate facilities at hand for immediate examination of more specialized type. His judgment as to whether a patient with frequent stools should be admitted to a hospital should be guided by the patient's general condition, by the severity of the diarrhea and by the presence of either of the other cardinal symptoms, namely fever or cramps. If the latter are present, further investigation is mandatory. A moderate percentage of patients in tropical areas may have only toxemic symptoms at the onset, and attention may not be directed to the bowel until loose stools appear, sometimes as long as two days later. Early symptoms may suggest dengue fever or malaria or other conditions manifested by fever and headache, and for that reason repeated questioning may be needed to get the patient to mention his first bowel symptoms.

The earliest positive diagnosis of bacillary dysentery is made by proctoscopy or proctosigmoidoscopy. Contrary to the common conception of such an examination as part of the initial physical evaluation, the procedure is neither difficult nor painful in patients with diarrhea. It is done as easily as the routine rectal digital, and with no more bother. If the patient is allowed to empty his bowel immediately before the proctoscope is inserted, the bowel usually will be found perfectly prepared for examination. An enema as preparation merely fills the bowel with poorly absorbed water, thereby creating interference. Furthermore, an enema may alter somewhat the true appearance of the bowel mucosa. I have found the knee-chest position most practical for the patient during the examination under field conditions. In most patients the diagnosis can be made with the instrument inserted no more than 5 inches, and the procedure requires only a few minutes. Specific diagnosis by culture of the stool usually requires two or more days, and there is a fair chance that the cultures will be negative. The early stools often do not contain pus or blood either grossly or microscopically. It is neither necessary nor desirable to wait for characteristic stools to appear before making the working diagnosis of bacillary dysentery.

SUBJECT MATERIAL

The material covered in this paper includes 87 cases of shiga dysentery seen in an army station hospital in New Guinea between May 1944 and March 1945. The number studied gives no idea of the incidence of the disease, since it includes no borderline cases and because many patients are treated in dispensaries. The purpose of the study was to increase the speed of accurate differentiation of bacillary dysentery from other forms of dysentery and to determine visually the response of the mucosal lesions to various types of treatment. Diagnostic proctoscopy was performed as soon as possible after it was suspected that the condition was the result of infection of the bowel. In some patients this could be done within a few hours after the onset of symptoms; in others who had been treated for a time in more forward areas or at local dispensaries such examinations were necessarily delayed. Subsequent to the initial examination, proctoscopy or sigmoidoscopy was performed at short intervals in order to follow the changes occurring during treatment.

The symptomatology of bacillary dysentery is variable, depending on the strain of organism, its virulence, the size of the initial infection and the general condition and resistance of the patient. One group of symptoms includes those caused by the acute toxemia resulting from absorption of exotoxin of Shigella dysenteriae or of small amounts of the endotoxin of Shigella paradysenteriae. To such toxemia can be attributed the fever, headache, chill, malaise, nausea, vomiting and generalized aches seen, in that general order of frequency. As a rule the acute toxic symptoms subside spontaneously in one to three days. The second group of symptoms is the result of bowel involvement and includes frequent bowel movements, cramps and the passage of bloody and purulent stools. Such diarrhea is watery and urgent, and in those cases in which a large amount of tenesmus is present there is usually an unusual amount of low rectal involvement. Stools number from one to forty each twenty-four hours, usually averaging between five and ten in that time. Fever ranging from 99.5 F. to 105 F. averages about 101.2 F. maximum. The cramps in shiga dysentery are nearly always low abdominal, although occasionally they occur in the mid or upper abdomen. Headache may be very severe, as indicated by the fact that 1 patient in our series had an admitting diagnosis of possible meningitis.

Physical findings are of little help in making a positive diagnosis of bacillary dysentery. Often, however, a tenderness over the descending colon helps to confirm the suspicion that the bowel is the source of the initial headache and fever. It was a little surprising to find the spleen palpable in 7 of the 87 cases in the series. No malarial plasmodia were found in thick blood smears, and as the acute toxemia disappeared the splenic enlargement could no longer be demonstrated. Two patients had algid or cholera-like dysentery with subnormal temperature, blood pressure falling to the shock level, clammy profuse perspiration and a severe prostrating diarrhea. One came on three days after herniorrhaphy, and the other developed three days after appendectomy for suppurative appendicitis. In addition to the use of large quantities of parenteral saline solution, the administration of sodium sulfadiazine intravenously led to dramatic improvement within twenty-four hours.

LABORATORY FINDINGS

In this series of cases routine laboratory tests were done but had only negative diagnostic value. The leukocyte counts ranged from 3,300 to 17,500, with an average value of 8,500. Microscopic examinations of stools showed no parasites or ova. Red and white blood cells and macrophages frequently were visualized.

In the 87 cases studied stool cultures taken before treatment was started were positive for Shigella organisms in 48.2 per cent. Various strains of Shigella paradysenteriae were isolated in 40 patients. Shigella ambigua was found in 2 and, through accident, 3 patients did not have stool cultures taken before treatment was started.

PROCTOSIGMOIDOSCOPIC FINDINGS

The types of bowel lesions seen on proctoscopy depend on the stage of the disease, on the virulence of the organism and on whether or not chemotherapy has been used prior to the examination. There are several salient features on which the diagnosis may be based.

1. *Early Phase.*—Even when the symptoms have been present only a few hours, the common features are found. Mucosal edema and diffuse hyperemia form the background. The edema may be barely discernible or the mucosa may present a waterlogged appearance. Usually the capillary dilatation is diffuse and the usual vascular pattern of the mucosa is lost. The mucosa may present a pink to red velvety surface. Punctate, flame-shaped or ecchymotic hemorrhages are visible either in the mucosa or beneath it. Studded through the mucosal surface in this acute phase there may be the most characteristic lesions of all, miliary mucosal abscesses of pin point or pin head size. These are creamy in color, slightly elevated and probably represent localized accumulations of leukocytes. These "abscesses" in the untreated cases become topped by shallow ulcerations. When the patient receives suitable chemotherapy the "abscesses" may disappear quickly or be replaced by reddish "granulation." Early, in the more acute cases, there may be a diffuse superficial necrosis of the mucosa, with dissolution of the normally smooth surface and the formation of a pseudomembrane which clings closely. This may be wiped free, leaving a red to purple raw mucosal surface which may be friable enough to bleed freely, giving frank blood mixed with pus or mucus in the lumen of the bowel. It is in the early acute phase of bacillary dysentery that the best opportunity for quick healing is offered. Up to a certain point in this infection the bowel mucosa may endure toxic changes without sustaining poorly reversible damage. After such damage has occurred, however, the lesions must run their own course, and their resolution is less quickly influenced by chemotherapy.

If a patient with bacillary dysentery receives no treatment, or if several days elapse before medical care is sought or treatment given, one of several things usually happens. The disease may be mild enough to run its course quickly without treatment, it may run a delayed course or it may reach an indolent ulcerative stage. It is the delayed course which shows best the middle phase of healing.

2. *Middle Phase.*—The mucosal changes in this phase are usually accelerated by chemotherapy. With or without treatment the lesions of the initial process clear in an order chronologically the opposite of their appearance. If first seen during this middle phase the mucosa may not have much residual edema, and fresh or fairly old granulations may have developed at the sites of previous mucosal necrosis or abscesses. These granulations vary in number and size. They are usually irregular in shape and separated by the fairly normal areas of mucosa not previously involved by necrosis. The granulations are usually a dusky red or purple, and in their centers superficial ulcers may or may not be seen. When present, such ulcers may vary from 0.5 mm. to over 1 cm. in diameter and may be round, oval or serpiginous. Their bases may be distinctly gray and dirty. The proximal surfaces of the valves of Houston are favorite sites for granulations and ulcers, although there is no regularity of location. A patient with much rectal tenesmus may have most of his mucosal lesions in the distal 6 cm. of the bowel.

As these lesions heal, the free pus and blood disappear from the lumen of the bowel and soon afterward the mucosal edema lessens. The diffuseness of the mucosal hyperemia as well as evidences of necrosis and pseudomembrane is lost. The abscesses and sometimes the hemorrhages vanish with only a trace remaining. Granulation fills in the ulcerations and may assume an elevated mulberry studded appearance. These dusky granulations usually become progressively lighter in color until a vague pink lymphoid type area remains. When this is no longer evident there is a restoration of the normal vascular pattern of the mucosa.

In 1 or 2 subacute cases of great severity fairly deep ulcerations of the mucosa were present, together with waterlogging edema of the interval mucosa, which ballooned over the edges of the ulcers, making them resemble an undermining type.

The most characteristic lesions of this phase are the ulcerations and the granulations which are part of the healing process. The granulations may be reluctant to disappear from the mucosa even though there may be no coincidental clinical symptoms. A red to purplish dry granulation may lend to considerable areas of the mucosa a mulberry appearance, while at the same time there may be no diarrhea or cramps. Such lesions often persist for many days after the patient could be considered cured symptomatically.

Immediate diagnosis and prompt adequate chemotherapy are necessary to prevent the development of such slowly reversible lesions.

3. *Late Phase.*—In a number of cases of untreated acute bacillary dysentery there occurs an indolent ulcerative phase in which the ulcers are more discrete. Such ulcers usually have a dirty gray base and the edges and interval mucosa may show little or no reaction. Sometimes persistent slowly healing ulcers leave superficial scarring, as manifested by areas of pallor and loss of the normal blood vascular pattern. These areas may be made more prominent by surrounding hyperplasia of lymphoid tissue. In our experience it is uncommon to see much late thickening of mucosa or of valve edges. Only 1 patient was seen with residual formation of tiny globular retention cysts in the mucosal surface.

DIFFERENTIAL DIAGNOSIS

In the differential diagnosis of the many conditions associated with diarrhea and the other symptoms suggestive of bacillary dysentery, one might mention amebic dysentery, gastroenteritis of undetermined cause, salmonella infections such as paratyphoid fever, idiopathic ulcerative colitis, cholera, staphylococcic food poisoning, epidemic diarrhea with nausea and vomiting, schistosomiasis, segmental enteritis, bowel neoplasms, balantidiasis, irritable bowel and malaria. In New Guinea bacillary dysentery must be differentiated most commonly from acute amebic dysentery, acute gastroenteritis, staphylococcic food poisoning, salmonellosis and epidemic diarrhea. In 90 per cent of instances we feel it is possible to make an early positive diagnosis of shiga dysentery by means of the proctosigmoidoscope.

As a rule in gastroenteritis, staphylococcic food poisoning and epidemic diarrhea we have found only mild edema and mild hyperemia of the mucosa.

In the proctoscopic examination of 11 cases of proved paratyphoid fever with diarrheic symptoms the chief value was a negative one in that it was possible in each instance to exclude bacillary dysentery. In 3 of these confirmed cases the diagnosis of paratyphoid fever was made by the proctoscopic picture and in 1 it was suspected. The paratyphoid fever cases with positive findings on proctosigmoidoscopy exhibited a mottled lymphoid mucosal hyperplasia of moderate degree. This occurred irregularly and was light pink, not red as one expects in ordinary hyperemia. Two of the patients had numerous small, round and oval ulcers rather evenly distributed on the tops of the lymphoid mucosal prominences.

Differentiation of borderline types of acute amebic dysentery is sometimes difficult. The usual type has characteristic discrete ulcerations which tend to be deeper and more evenly distributed than the ulcers of shiga dysentery There is more tendency to thick hyperplastic mucosal involvement, and it is common for the interval mucosa to be quite normal in appearance. Quite often the discrete ulcers have blood oozing out of their bases while at the same time no pus is visible. This is hardly ever seen in shiga dysentery. In the advanced cases of amebic colitis the deeper involvement gives a characteristic undermining of the ulcers and sometimes deep necrotic and sloughing areas with exposure of the muscular layers of the bowel.

EVALUATION OF RESPONSE TO TREATMENT

In studying the response of bacillary dysentery with and without various forms of treatment, it is necessary to take into consideration the fact that in many instances the disease is mild and more or less self limited and that the symptoms may clear spontaneously. In other cases the clinical symptoms clear spontaneously but the demonstrable mucosal lesions may persist. In previous studies [1] the criteria for response to treatment have been the cessation of symptoms and the length of hospitalization. Unless proctosigmoidoscopic studies have been made, such criteria are misleading. It can be demonstrated repeatedly in this condition that, although the relief of cramps and diarrhea by sulfadiazine is usually prompt or dramatic, the healing of the mucosal lesions seems dependent on how much time has elapsed between the onset of symptoms and the institution of chemotherapy. When the diagnosis is made and treatment started within twenty-four hours after onset of symptoms, the objective response to therapy may be as dramatic as was the relief of symptoms. If several days have passed during which symptoms were ignored, misunderstood or inadequately treated, the initial phase of toxic changes passes and ulcerations become more definite. The healing of such ulcerations passes through the usual phases of healing seen in any type of ulcer and naturally this requires time. The golden period of treatment of bacillary dysentery lies in the first twelve to twenty-four hours after onset of symptoms. This fact again emphasizes that proper treatment is dependent on rapid diagnosis before the stool culture can be of help.

In the attempt to evaluate the objective response to treatment of this series of cases, four groups were studied: (1) cases without chemotherapy, (2) cases with sulfaguanidine therapy alone, (3) cases treated with sulfadiazine alone and (4) cases treated with a combination of sulfadiazine and sulfaguanidine. We had no other suitable chemotherapeutic agents available.

General therapeutic measures common to all the groups included bed rest and liquid diet for twenty-four hours and in several instances intravenous administration of isotonic solution of sodium chloride. Paregoric and bismuth were not used in treatment. After the first day the diet was increased rapidly to full quantities.

When sulfaguanidine was given the patient received 4 Gm. every three hours for four doses, then 2 Gm. every four hours for a total of seventy-two hours, totaling 46 Gm. When sulfadiazine was used, equal weights of sodium bicarbonate were given. The initial dose was 4 Gm. of sulfadiazine followed by 2 Gm. every four hours for four doses, then 1 Gm. every four hours for four doses and 1 Gm. every six hours for seven doses, making a total of 23 Gm. in seventy-two hours. In a few instances maintenance doses of sulfadiazine were continued for up to a week. With the combined treatment, the usual sulfadiazine routine was followed for three days. During the last day of these, the sulfaguanidine routine was given and continued the fourth and fifth days of treatment, making a total of five days of therapy. These amounts were used without regard for the weight of the patient. An increase in the fluid intake to 3,000 cc. daily was encouraged, and in most instances subsequent leukocyte counts and urinalyses were made. Determinations of blood sulfonamide levels were made on many of the patients and the highest levels attained during sulfadiazine therapy ranged from 6 mg. to 22 mg. per hundred cubic centimeters. No reactions to sulfadiazine were encountered. Two patients receiving sulfaguanidine had drug reactions:

[1] Paulley, J. W.: Treatment of *Bacillary Dysentery* in the Middle East, Lancet **2**:592 (Nov. 21) 1942. Poth, E. J.; Chenowith, B. M., Jr., and Knotts, F. L.: A Preliminary Report on the Treatment of Bacillary Dysentery with Succinylsulfathiazole, J. Lab. & Clin. Med. **28**:162 (Nov.) 1942.

1 manifested by headache, nausea and fever sustained at about 101 F., the other manifested by chilliness, fever to 104 F., headache, backache and slight splenic enlargement. Other sources of fever were excluded, and the temperature and spleen returned to normal after discontinuance of the drug. The second patient had had an initial therapeutic course of sulfadiazine without untoward reaction.

SYMPTOMATIC RESPONSE

In evaluating the relief of symptoms, record was kept of the disappearance of fever, cramps and diarrhea and of the time required for the establishment either of constipation or of normal bowel habit. This can be shown best by table 1. It may be seen that while some of the untreated cases subsided very promptly, most of them were classed as slow in response. The relief during sulfaguanidine therapy was faster than when none was administered. The remarkable relief of symptoms during sulfadiazine or combined sulfadiazine and sulfaguanidine therapy seemed to be chiefly the response to sulfadiazine. These results were more remarkable than apparent from the figures. Because of the need for treating the sickest patients with the most effective means available, a large percentage of those treated with sulfadiazine were of the most severe type and some of them had extensive subacute lesions of relatively long duration.

OBJECTIVE RESPONSE

The objective response to therapy (table 2) was determined by repeated proctosigmoidoscopies made at one to three or four day intervals, depending on the rate of healing. From two to ten examinations were performed on each patient. Here again many of the cases had been existent for sufficient time to render them rather resistant even to sulfadiazine. The extra time required for objective healing in these cases, all of which fell into the third and fourth therapeutic groups, elevated the average time required for clearing of the lesions treated with sulfadiazine alone or in combination. In those patients who had had their symptoms only a few hours before our diagnosis and treatment, the objective healing response was so swift and complete as to leave no conceivable doubt as to the effectiveness of the treatment. In even the worst of such necrotizing mucosal processes, if sulfadiazine treatment could be begun within twelve to twenty-four hours after onset of symptoms it was usually possible to anticipate objectively complete clearing of the lesions and restoration of a normal bowel within three to ten days.

Even with the most severe cases included in the sulfadiazine group, the average of seven days required for healing was significantly less than the average time required for disappearance of the lesions in cases treated with nothing or with sulfaguanidine alone.

Review of the 14 patients to whom no treatment was given shows that 7 had a mild form of bacillary dysentery in which demonstrable lesions subsided spontaneously in from six to fourteen days. Seven of the patients had symptoms and lesions which continued long enough to lead to a sense of shame at depriving them of treatment. Two of these finally cleared spontaneously. The other 5 had to have chemotherapy to terminate their symptoms and lesions. Sulfaguanidine, when finally given, cured both within a few days. With the help of chemotherapy these lesions healed in the eighth to twentieth days. In the last 5 of the 7 patients there was no doubt of the indolence of the process up to the time sulfaguanidine was given, although it is entirely possible that the lesions would have cleared ultimately without chemotherapy.

EFFECT OF CHEMOTHERAPY ON STOOL CULTURES

The question of persistence of positive cultures of the fecal content of the bowel is an important one from the point of view of direct transmission and subsequent carrier states. In our experience sulfadiazine is just as effective as sulfaguanidine in rendering such stool cultures negative. Of 87 patients, 42 had positive stool cultures before treatment. After treatment with sulfaguanidine, of 8 patients with positive stools before treatment, all had negative stools after treatment. Of 20 patients having positive stool cultures, sulfadiazine rendered the cultures negative in 18. The other 2 patients had to be evacuated for other reasons before the cultures became negative. Of 10 patients having positive stool cultures before treatment, all had negative cultures after the combined use of sulfadiazine and sulfaguanidine. In several patients with serial cultures taken twice daily by way of the proctoscope, it was found that sulfadiazine therapy rendered cultures negative within twenty-four to thirty-six hours. Such effectiveness decreases the period during which it is necessary to isolate such patients.

Table 1.—*Relief of Symptoms of Shiga Dysentery During Various Forms of Treatment*

	Symptomatic Relief					
Treatment	Dramatic, 1 Day	Prompt, 2-3 Days	Moderate, 4-5 Days	Slow, More Than 5 Days	None	Total Cases
None	0	3	1	6	4	14
Sulfaguanidine	0	6	9	5	0	20
Sulfadiazine	22	9	1	2	0	34
Sulfadiazine plus sulfaguanidine	14	2	2	1	0	19

Table 2.—*Healing of Mucosal Lesions of Shiga Dysentery as Demonstrated by Repeated Proctosigmoidoscopies During Various Forms of Treatment*

Case Groups	Hospital Stay, Average Days	Time Required for Healing	
		Average Days	Range, Days
No treatment	15.0	11.3	6-20
Sulfaguanidine	16.1	10.2	3-16
Sulfadiazine	12.9	7.0	2-14
Sulfadiazine plus sulfaguanidine	15.6	10.8	3-21
All cases	14.9	9.8	2-25

QUESTION OF CHRONIC BACILLARY DYSENTERY

A number of years ago during an outbreak of bacillary dysentery in a state hospital 2 patients with proved shiga dysentery continued to have persistent dysenteric symptoms. One, an old man, died of inanition about four months later. The second, a man aged 60 who remained in an acute manic phase of a manic-depressive psychosis, died three months after the onset of his dysentery. At autopsy in both patients many chronic ulcers were found scattered through the colon. Some of the ulcers were deep, some were shallow. Three other cases, not included in the present series, deserve comment. One patient for three weeks had had inadequate treatment prior to his admission for a severe dysentery caused by Shigella ambigua. Although he improved considerably on adequate chemotherapy, he continued to have symptoms and persistent shallow ulcerations of the mucosa during the sixty days of our observation before his evacuation. The second patient had had an acute bacillary dysentery five months before being seen by us, and in those months he had had about ten brief recurrences with intermittently positive stool cultures for Shigella paradysenteriae. He had never been hospitalized or examined with the proctoscope and treatment had been haphazard. On admission to the hospital after five months of recurrent symptoms chronic mucosal ulcerations were demonstrated by proctoscope although he was having formed stools at the time. Even on adequate treatment these lesions required over three months to heal. The third patient had had repeatedly recurrent episodes of dysentery following an initial acute attack four months before. He had received sulfaguanidine therapy for demonstrable mucosal ulceration in two other hospitals where he had been treated. The first proctoscopy by us following his last episode of diarrhea revealed that the bowel mucosa was normal except for several vaguely outlined pallid areas, and many stool cultures were negative. Following an operation for ingrown toenails, he developed acute bacillary dysentery with fever, cramps, many typical stools, culture positive for Shigella paradysenteriae and proctoscopic findings of hyperemia and edema which accentuated the previously noted pallid areas. Sulfadiazine quickly controlled his symptoms, and the bowel mucosa regained the appearance which it had had when it was first seen. We felt that this represented a chronic bacillary dysentery with acute exacerbation. These patients are cited chiefly to illustrate the belief that bacillary dysentery can give rise to one form of chronic ulcerative colitis. The first 2 had had no chemotherapy, and the last 3 had received late, haphazard or inadequate chemotherapy. Such cases emphasize the need for immediate diagnosis and prompt adequate chemotherapy in this disease.

CONCLUSIONS

1. The early diagnosis of bacillary dysentery can be made rapidly and accurately by proctosigmoidoscopy. Such examination should be made promptly whenever a patient complains of diarrhea and abdominal cramps either with or without associated fever. The use of the proctoscope for the immediate diagnosis of bacillary dysentery is as practical as the use of an otoscope or ear speculum in the diagnosis of otitis media.

2. Preliminary diagnostic and frequent subsequent proctosigmoidoscopies were made in cases of bacillary dysentery seen in New Guinea.

3. Pathologic mucosal changes were visible and diagnostic within two to twenty-four hours after the onset of symptoms.

4. In this series of 87 cases, 48 per cent had negative stool cultures and might have had incorrect diagnoses if proctoscopy had not been performed.

5. Repeated proctosigmoidoscopies were made to determine the comparative effects which various types of therapy have on objective healing of the bowel lesions. Fourteen cases were treated with bed rest and a low residue diet. Twenty cases were treated with sulfaguanidine alone, 34 with sulfadiazine alone and 19 with a combination of the two sulfonamides.

6. It is felt that the golden period for effective therapy in this condition occurs during the first twenty-four hours of symptoms. At that time the initial toxic changes in the mucosa are most easily reversible. If effective treatment is postponed until stool cultures are reported, the consequent ulcerative changes require much extra time to disappear and in a few cases such lesions become very resistant to treatment. Three patients were encountered with what seemed to be a form of chronic ulcerative colitis due to shiga dysentery.

7. Effective early treatment with sulfadiazine usually leads to prompt or dramatic cessation of diarrhea and cramps. However, symptomatic relief is not paralleled by objective healing of the mucosal lesions, which to heal may require three days or three weeks or longer depending on the length of time elapsing between the onset of symptoms and the institution of therapy. The objective healing of the mucosal lesions was significantly faster during chemotherapy, especially during the use of sulfadiazine. This was attributed to the readier access of the soluble sulfonamide to the causative organisms by way of the capillaries.

8. The immediate proctosigmoidoscopic diagnosis of bacillary dysentery permits prompt specific treatment, quick relief of symptoms, accelerated objective healing, a shorter period of hospitalization and reduction of the chances of mortality.

9. Empirical sulfonamide treatment of dysentery before proctosigmoidoscopic examination has established the diagnosis is to be deprecated because of the danger of overlooking causes which may be of more serious significance than bacillary dysentery.

PARATHYROID ADENOMA AND HYPERTROPHY OF THE PARATHYROID GLANDS

H. MILTON ROGERS, M.D.
Fellow in Medicine, Mayo Foundation
Rochester, Minn.

The clinical recognition of hyperparathyroidism depends on interpretation of its protean manifestations. These have been divided into (1) those symptoms resulting from chemical alterations in the blood, (2) those symptoms resulting from involvement of the urinary tract and (3) those symptoms resulting from involvement of the skeleton.[1] At first the disease was recognized only in instances of far advanced skeletal disease. More recently a considerably larger group of cases have been reported in which renal symptoms predominated and skeletal involvement was minimal or absent. Albright, Aub and Bauer[2] have pointed out that hyperparathyroidism with bone disease may occur without evident renal lesions and that hyperparathyroidism with renal lesions can occur without bone involvement. It is therefore apparent that neither osseous nor renal lesions need necessarily be conspicuous in hyperparathyroidism. Keating and Cook[3] have mentioned one proved instance of hyperparathyroidism in which there was no evidence of bone or renal involvement. In any case in which hyperparathyroidism is suspected from the clinical manifestations, confirmation of the diagnosis depends on the interpretation of chemical analysis of the blood and urine for calcium and phosphorus.[4]

From the Section on Pathologic Anatomy.

Dr. H. E. Robertson, Dr J. W. Kernohan and Dr. F. Raymond Keating Jr. contributed advice in the arrangement of this paper.

In the absence of conspicuous renal or skeletal disease, hyperparathyroidism could be expected to produce only the symptoms attributed to hypercalcemia per se. These include nausea, vomiting, weakness, lethargy and anorexia and have been most conspicuous in instances of severe or acute hyperparathyroidism, spontaneous or experimentally produced, of the type sometimes referred to as parathyroid poisoning.

Parathyroid overdosage was first produced in dogs by Collip[5] in 1926. A similar picture was also produced by Collip[6] by the injection of certain inorganic salts. Later it was demonstrated by Hueper[7] that dogs dying of acute parathyroid poisoning presented metastatic calcifications in organs such as the kidneys, lungs and stomach. Vomiting, anorexia, failure of the kidneys and death in a state of uremia from parathyroid overdosage in acute animal experiments were described by Thomson and Collip.[8] The findings at necropsy in dogs dying from acute experimental hyperparathyroidism were described by Cantarow, Stewart and Hausel.[9]

It is probable that the case reported by Dawson and Struthers[10] is the first example of acute hyperparathyroidism occurring in man due to parathyroid tumor. Listlessness, drowsiness, fever and vomiting have been reported in a boy 5 years of age given 100 units of parathyroid injection daily for six days by error.[11] Recovery occurred when administration of the parathyroid injection was discontinued. Hanes[12] in 1939 reported the first example of death from parathyroid poisoning in man that was observed clinically. In his case hyperparathyroidism was diagnosed but, before operation could be performed, the patient became extremely weak and nervous, had elevated temperature and generalized aching and died. At necropsy an adenoma of the parathyroid was found. In addition there were "widespread injury necrosis and calcification of connective tissue, especially that forming the basement membrane of the parenchymatous organs and the arteries of medium and arteriolar size." Hepatic focal necrosis was present. Calcification was present in the kidneys and myocardium to a high degree. Calcium deposits of a lesser degree were present in the stomach and lungs. There was widespread calcification of the media of the arterioles in the heart, kidneys and lungs.

Oliver[13] has described 2 cases of death from acute hyperparathyroidism. The clinical features were vomiting, anorexia, loss of weight, asthenia, constipation and mental retardation. Fever, drowsiness and tachycardia were present. At postmortem examination a chief cell adenoma of the parathyroid gland was found with metastatic calcification in the kidneys, heart, lungs, stomach and arterioles.

The fifth case of acute hyperparathyroidism to be confirmed by necropsy was reported in 1940 by Smith and Cooke.[14] For two years the patient had noticed limping, pains in the legs and constipation. These were followed by abdominal pain, vomiting, tachycardia and delirium. An adenoma of the parathyroid composed of chief cells was found at necropsy. There was metastatic calcification of the kidneys and the pancreas.

It is my purpose in this paper to present the findings in 2 cases of probable acute hyperparathyroidism associated with duodenal ulcer. This coexistence has not been reported previously. Castleman and Mallory,[15] however, cited chief cell hyperplasia (secondary hyperplasia) of mild degree occurring in 2 cases in which there were duodenal ulcers.

REPORT OF CASES

CASE 1.—A Negro man aged 36, first admitted to the Mayo Clinic Nov. 11, 1943, for seven years previously had noted intermittent epigastric pain, usually relieved with alkaline powders. In the year preceding admission the pain had become more severe than it had been before. He was said to have had syphilis in 1923 and to have received antisyphilitic treatment.

The results of the physical examination disclosed a temperature of 98 F., pulse rate 66 beats per minute and blood pressure 110 mm. of mercury systolic and 80 diastolic.

The tonsils, which were large, were infected. The remaining examination gave negative results.

The urine had a specific gravity of 1.020, its reaction was acid and it was negative for albumin and sugar and on microscopic examination. A complete blood count was normal. The Kahn, Kline, Hinton and Kolmer reactions were all negative.

A roentgenographic examination of the thorax gave negative results. Gastrointestinal roentgenograms revealed the presence of a duodenal ulcer, but there was no evidence obtained of pyloric obstruction.

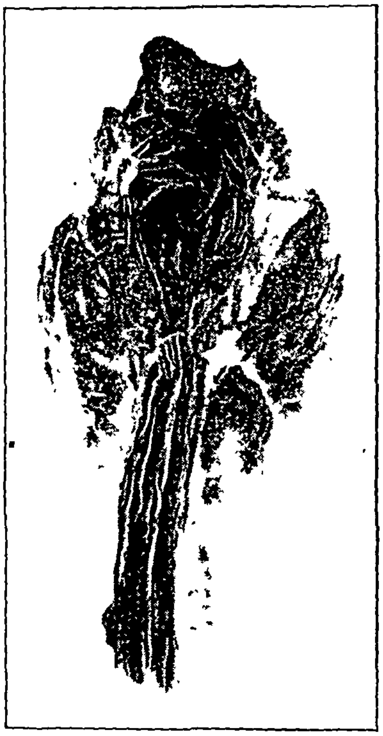

Fig. 1 (case 1).—Posterior view of the organs of the neck and adenoma of the right inferior parathyroid. The esophagus has been opened. Both lobes of the thyroid are seen.

The patient was hospitalized and routine treatment for ulcer was started. Tonsillectomy was performed on November 15. The postoperative course was uneventful for three days but then severe, continued vomiting developed. This was not associated with epigastric pain or nausea. It occurred after eating and at times lasted for several hours. The vomiting continued for eight days and then stopped.

The patient was well for two months after dismissal, but then epigastric distress recurred. This continued intermittently until July 1944, when it necessitated hospital care elsewhere. On his entering the hospital, administration of an ulcer diet with milk, calcium and magnesium phosphate was begun. After two days of this regimen, persistent vomiting developed and remained unabated for three weeks' time in spite of all treatment. Roentgenographic examination at this time again revealed a duodenal ulcer but no retention of barium in the stomach.

The vomiting ceased after dismissal from the hospital, and on Aug. 11, 1944 the patient was readmitted to the Mayo Clinic. The results of reexamination were unchanged except that a loss of 25 pounds (11.3 Kg.) was noted since last admission. He appeared apathetic and listless at this time. Questionable enlargement of the thyroid was noted. The blood pressure ranged from 140/80 to 170/110.

The urine was normal except for an occasional hyaline and granular cast. The blood count was normal. The Kline, Kahn, Hinton and Kolmer reactions were still negative. The concentration of urea was 38 mg. per hundred cubic centimeters of whole blood. The concentration of chlorides was 578 mg. per hundred cubic centimeters of plasma. The carbon dioxide combining power was 57.9 volumes per cent. The total acidity of the gastric contents was 82; free hydrochloric acid 69, no blood. The duodenal ulcer was again visualized, but no gastric retention was present.

The patient was hospitalized, and administration of an ulcer diet with aluminum phosphate gel and Sippy powders was begun Five days after admission, persistent vomiting reappeared. This, as before, was unaccompanied by pain and associated with only slight nausea. Throughout the period of hospitalization the patient had a peculiar listlessness, weakness and apathy which was unexplained. Psychiatric examination revealed evidence of an agitated depression, which had been increasing in severity for the past two months.

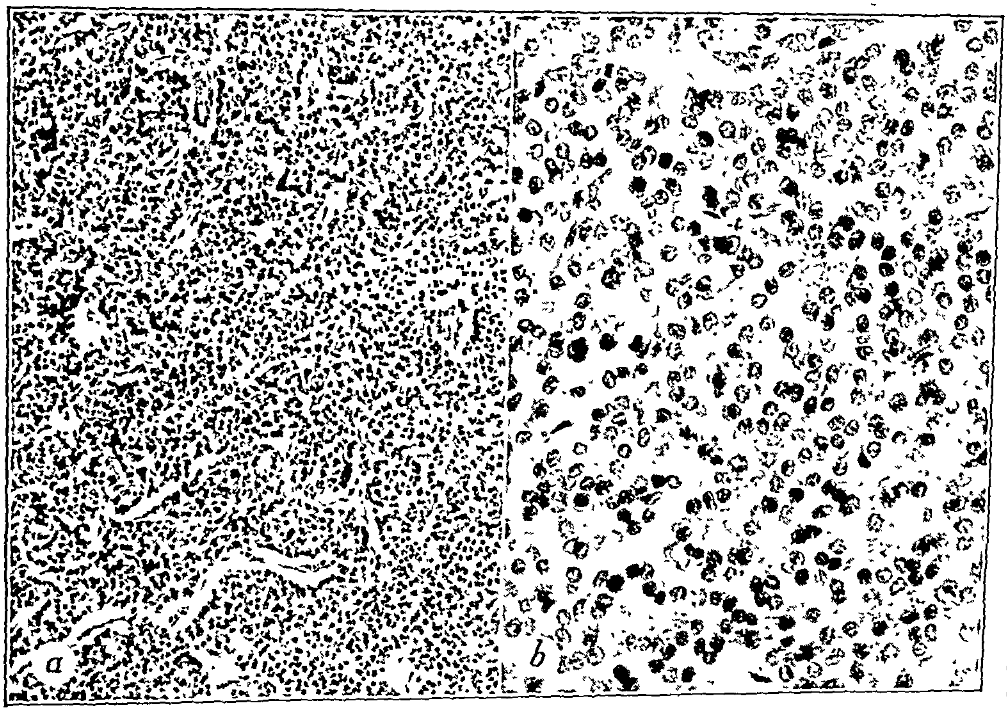

Fig. 2 (case 1).—*a*, adenoma of the parathyroid gland composed of chief cells (× 120); *b*, chief cells in adenoma of the parathyroid (× 350).

The vomiting, listlessness and apathy continued. In addition, headache appeared and the patient became disoriented. A hepatic function test was done on August 21, and pronounced retention of dye (sulfobromophthalein method) was found. The serum bilirubin was 1.5 mg. per hundred cubic centimeters direct and 0.3 mg. indirect. On August 27 for a short period he was unable to see. The temperature was now elevated for the first time and reached 101.6 F. in the evening. The blood pressure was now 145 systolic and 85 diastolic.

The patient became much worse on August 28 and lapsed into a semicomatose state. A roentgenogram of the thorax revealed bilateral congestion and parenchymal consolidation of the right lung, which were interpreted as indicating pneumonia. Administration of penicillin was started. A roentgenogram of the skull was negative. The concentration of urea had risen to 96 mg. per hundred cubic centimeters of blood and the concentration of chlorides was 611 mg. per hundred cubic centimeters of plasma. The carbon dioxide combining power was 75.8 volumes per cent. The serum bilirubin was 3.8 mg. per hundred cubic centimeters direct and 0.4 mg. per hundred cubic centimeters indirect. The serum lipase was 0.6 cc. of sodium hydroxide per cubic centimeter and the serum amylase was 160 units. There was dye retention, grade 4 (on the basis of 1 to 4, in which 1 designates the least and 4 the greatest retention), by the sulfobromophthalein method. The cerebrospinal fluid was clear with globulin positive; the total concentration of protein was 90 mg. per hundred cubic centimeters; the fluid was negative for blood; lymphocytes numbered 2 per cubic millimeter; the colloidal gold reaction was 0111100000; the initial pressure was 6 cm. of water; the pressure on compression of the jugular veins was successively 28, 10 and 8 cm. of water; the final pressure was 6 cm. of water.

The patient's condition became critical, with the rectal temperature rising to 105.6 F. Coma developed and vomiting continued. The output of urine, which had been good and was recorded as 3,600 cc. on August 28, dropped to 400 cc. on August 29 and to 200 cc. on August 30. The concentration of urea rose to 160 mg. per hundred cubic centimeters of blood and the serum bilirubin was 5.96 mg. per hundred cubic centimeters direct and 2.5 mg. per hundred cubic centimeters indirect on August 29. Death occurred on the morning of August 31 (nineteen days after admission).

At the postmortem examination the following conditions were deemed significant: an adenoma of the right inferior parathyroid (fig. 1); hypertrophy of the kidneys (right 405 Gm., left 400 Gm.); bronchopneumonia (right grade 3, left grade 1); mild icterus; healed duodenal ulcer; focal hemorrhage and infarct of the right cerebellar peduncle; thrombosis of a branch of the right pulmonary artery with calcification of the thrombus.

The adenoma of the right inferior parathyroid measured 3 by 1.5 by 1.7 cm. and weighed 4.12 Gm. It was light brown. The cut surface was also light brown and homogeneous throughout. The remaining parathyroids were normal in size and color.

In the lower lobes of both lungs there were irregular gray regions suggesting pneumonia. There was an antemortem thrombus occluding the pulmonary artery to the right lower lobe.

In the duodenum there was the scar of a healed ulcer located 1 cm. below the pylorus on the posterior surface.

The kidneys were enormous, the two organs together weighing 805 Gm. against a calculated normal of 400 Gm. The surfaces were pale brown and smooth. On section the cortex measured 0.8 cm. in thickness.

Microscopic study revealed the following findings (figs. 2 *a* and (*b*). The right inferior parathyroid was composed almost entirely of chief cells. In most regions they were arranged in solid masses, but often they were grouped in small cords and there was a tendency to assume a glandular pattern. Adipose connective tissue cells were practically absent. The stroma was sparse in some regions but more abundant in the glandular portion of the adenoma. Blood vessels were numerous. Only a few groups of oxyphil cells were present. The cytoplasm of the chief cells was sparse. In only an occasional cell were there deposits of glycogen. The remaining parathyroids were normal.

In the lungs there was bronchopneumonia in both lower lobes. The more striking finding, however, was the widespread calcification of the walls of the small and medium sized arteries (fig. 3). The deposits were in the media and involved the entire circumference of the vessels. There was also a widespread deposition of fine particles of calcium within the alveolar septums. These alveolar deposits were well demonstrated by von Kossa's specific stain for calcium. In the thrombus within the pulmonary artery to the right lower lobe there was pronounced calcification.

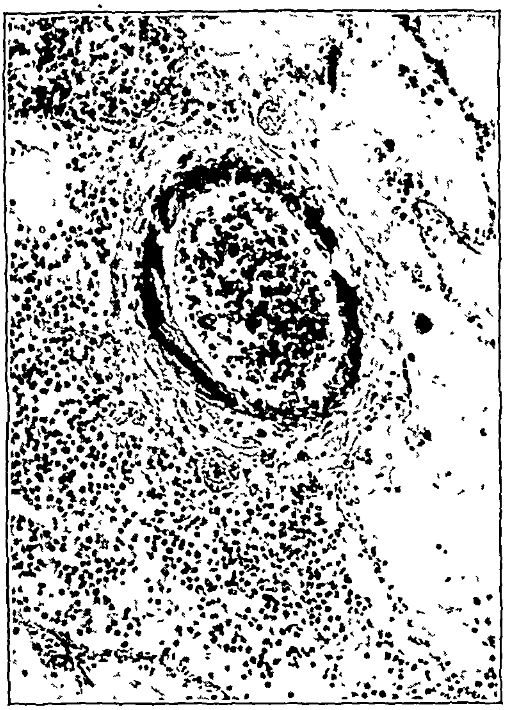

Fig. 3 (case 1).—Calcification of small pulmonary artery and bronchopneumonia. Calcification in the alveolar septums also can be seen (× 160).

In the liver, occasional bile canaliculi were distended with bile thrombi. Atrophy of the central zones was present in a minimal degree.

All sections of the kidneys revealed widespread deposition of calcium within the tubules and within the epithelial cells lining the tubules. In an occasional glomerulus there were deposits of calcium, and rarely a small artery presented medial calcification One small region of fairly recent infarction was almost completely calcified. Aside from these changes there was no evidence of recent or earlier renal disease.

The former duodenal ulcer was covered by intact mucosa. The pancreas was normal.

In decalcified microscopic preparations of the vertebrae and sternum there were disorganization of architecture and irregular distribution of calcium.

Case 2.—A white man aged 53, admitted to the Mayo Clinic on June 4, 1945, complained chiefly of epigastric pain and vomiting of two years' duration. In 1942 he had injured his back while employed as a miner. Roentgenographic examination at that time was reported to have revealed a chip fracture of the first and third lumbar vertebrae. Three weeks after this injury, while he was confined to bed, there developed vomiting, unassociated with pain, which persisted for one month. Intermittent epigastric pain continued for two years, occurring two to three hours after meals and relieved with alkali. There had been frequent episodes of vomiting during this time. In the past three months both the pain and emesis had become more severe, the latter not being associated with nausea. For two years there had been nocturia one to two times daily. Recent loss of 10 pounds (4.5 Kg.) had been noticed. For ten days prior to his admission, abdominal pain and severe vomiting had been present.

The patient's temperature was 98 F., pulse rate 96 beats per minute, blood pressure 154/100 to 130/100. His heart, lungs and abdomen were apparently normal. The urine had a specific gravity of 1.015, its reaction was acid and it contained a small amount of albumin but no sugar. Occasional hyaline casts were present. There were 6 leukocytes per high power field. The concentration of hemoglobin was 15.8 Gm. per hundred cubic centimeters of blood; leukocytes numbered 7,800 per cubic millimeter of blood. The Kahn reaction was negative. The concentration of urea was 28 mg. per hundred cubic centimeters of blood. Analysis of the gastric contents gave total acidity 68, free hydrochloric acid 56, no blood. Roentgenographic examination of the thorax was negative. The gastrointestinal roentgenographic studies visualized a duodenal ulcer with a crater but no gastric retention.

An ulcer regimen and administration of aluminum phosphate gel were begun. For three days the patient did well, but then vomiting started and was continuous, even though on some days his diet consisted only of milk. He was hospitalized on June 18 for observation and possible operation.

As the symptoms did not improve with hospital care, operation was advised. On June 30, 1945 gastric resection was done for subacute perforating duodenal ulcer. Three days after operation the concentration of urea had risen to 114 mg. per hundred cubic centimeters of blood, with concentration of chlorides 644 mg. per hundred cubic centimeters of plasma and carbon dioxide combining power 60.7 volumes per cent. The concentration of protein was 6.2 Gm. per hundred cubic centimeters of serum. The patient appeared listless and lethargic. This condition became more severe on July 7. Recurrent and persistent vomiting was again noted. On July 8 he stopped eating, and it was difficult to get him to talk. On gastric lavage there was no retention. The urinary output remained good. On July 9 the patient became semicomatose, and there was evidence of shock. On July 10 he sank into a coma and his temperature rose to 105 F. The blood studies at this time revealed urea 232 mg. per hundred cubic centimeters of blood and carbon dioxide combining power 46.6 volumes per cent. Leukocytes numbered 13,200 per cubic millimeter of blood. The course thereafter was downward. His temperature rose terminally to 106 F., with death on July 10, 1945.

At the postmortem examination the significant findings were as follows: primary hypertrophy of the parathyroids and of supernumerary parathyroid glands; recent (ten day) partial gastrectomy for perforating duodenal ulcer; terminal bronchopneumonia; multiple calcifications of the dura mater; hypertrophy of kidneys

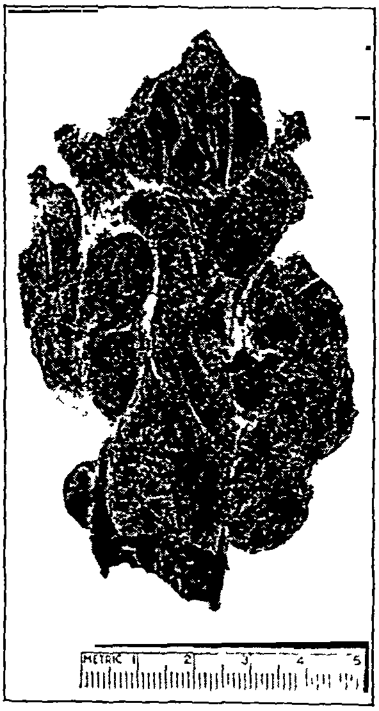

Fig 4 (case 2).—Posterior view of the organs of the neck, demonstrating hypertrophy of the parathyroid glands. The left superior and inferior parathyroid glands and the two right superior and the right middle parathyroid glands are seen. The esophagus has not been opened The left lobe of the thyroid is seen

The parathyroid glands presented a curious picture (fig. 4). On the left side there were three distinct glands designated as superior, middle and inferior. The left superior parathyroid measured 3.2 by 1.6 by 1.2 cm. From its upper lateral surface there was a tonguelike projection of parathyroid tissue measuring 1.2 by 0.4 by 0.2 cm. The left superior parathyroid with the tonguelike projection weighed 3.37 Gm. The upper part of the main portion was yellow-brown and homogeneous, while the lower third was darker brown and contained small cystlike cavities measuring up to 1 mm. in diameter. The left middle parathyroid measured 1.8 by 0.4 by 0.2 cm. and weighed 0.130 Gm. The left inferior parathyroid measured 0.7 by 0.4 by 0.2 cm. and weighed 0.09 Gm. These two glands appeared grossly like normal parathyroid tissue.

On the right side there were six distinct parathyroid glands. The largest of these, designated right middle parathyroid, showed extreme hypertrophy. It measured 5.7 by 2.0 by 2.7 cm. Its upper pole was pale brown, while the lower pole was dark brown. In it were two cysts filled with serous fluid; the larger one, in the upper pole, measured 2 by 1.5 by 1.5 cm. and the smaller one, in the midportion, measured 1.0 by 1.0 by 0.8 cm. The cyst walls were partially calcified. The gland weighed 14.9 Gm. after the cysts had been emptied. There were two small parathyroid glands lying on the superior and posterior surface of the right middle parathyroid gland but entirely separate from it. They might be designated right superior parathyroid glands. They measured 0.9 by 0.4 by 0.2 cm. and 1.0 by 0.6 by 0.3 cm. and weighed 0.110 Gm. and 0.150 Gm. respectively. Anteriorly and beneath the right middle parathyroid gland were three other distinct parathyroid glands. These might be designated as right inferior parathyroids. The largest two hung grapelike from the main tumor but were separated from it by bands of fibrous connective tissue. They measured 2.0 by 0.9 by 0.4 cm. and 2.0 by 0.6 by 0.4 cm. and weighed 0.730 Gm. and 0.690 Gm. respectively. The remaining right inferior parathyroid gland measured 1.0 by 0.4 by 0.2 cm. and weighed 0.150 Gm. (figs 5 and 6).[16]

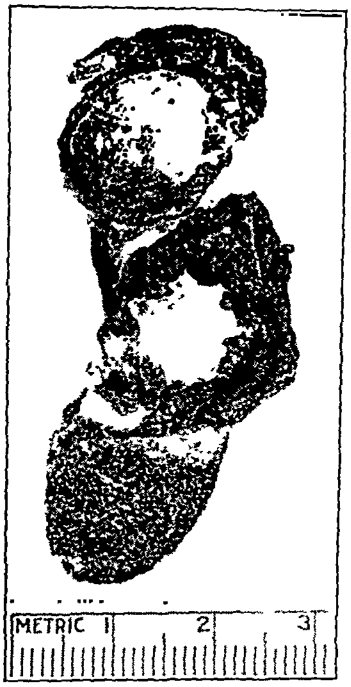

Fig. 5 (case 2).—The right middle parathyroid gland; two cysts are seen in the upper and middle poles.

The total amount of parathyroid tissue in this case weighed 20.32 Gm. as against a normal weight of about 0.14 Gm. I cannot find comparable reports in the literature of this number of supernumerary parathyroid glands.

In the lower lobe of the right lung there was increased consistency with corresponding decreased crepitation.

Two large ulcers were found in the duodenum, perforating on the pancreas.

The kidneys were pink-brown. The right weighed 250 Gm. and the left 290 Gm. There were many small adenomas measuring 1 to 4 mm. in diameter. Numerous peripelvic and parenchymatous cysts measuring from 1 to 2 mm. were present in both kidneys. Postmortem roentgenographic examination revealed diffuse nephrocalcinosis with the calcified regions measuring 1 to 2 mm.

There was calcification of the dura mater along the superior sagittal sinus and falx extending 1 to 1.5 cm. on each side. Small metastatic nodules of calcification up to 2 cm. in diameter were present on the inner surface of the dura mater.

The microscopic findings were as follows: All parathyroid tissue was composed of essentially the same type of large, clear cell (wasserhelle cell, described by Getzowa[17]) (fig. 8 *a* and *b*). The description of the cell fits well with that given by Castleman and Mallory and will be quoted:

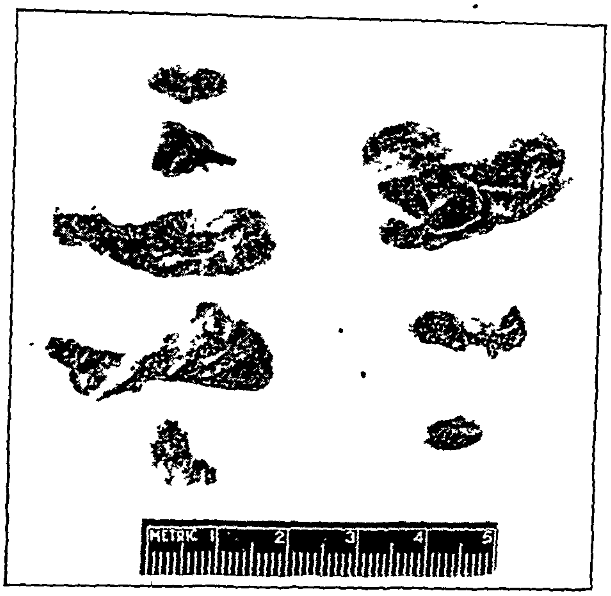

Fig. 6 (case 2).—Parathyroid glands; the right middle parathyroid gland is not shown; illustrated on the left are the right superior and right inferior glands and on the right the left superior, middle and inferior glands.

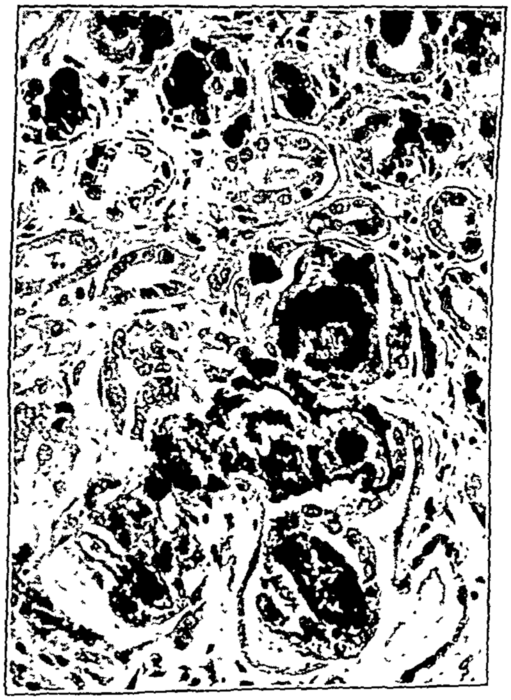

Fig. 7 (case 2).—Kidney with nephrocalcinosis of an extreme degree. The calcium is deposited in the tubular cells and in the lumen (X 235).

"The wasserhelle cell is polyhedral in shape, sharply demarcated by a thin basophilic membrane and varies from 10 to 40 microns in diameter, averaging 15 to 20 microns. Many of the cell boundaries are broken with resultant fusion, similar to the alveoli in pulmonary emphysema. In contrast to the variability in the size of the cells the nuclei, though often multiple, are round to slightly ovoid in shape, sharply outlined and moderately hyperchromatic with an eccentrically placed nucleolus. As a rule the nuclei are located in the end of the cells, that is contiguous to the stroma. This produces a characteristic pattern which resembles a branch of berries. The cytoplasm is clear except for a little light pink staining granular material. Many of their tiny granules are glycogen deposits. Similar granules are present within the nuclei. There is no fat except for a rare droplet in the stroma. The low power appearance of the histological sections is so similar to that of clear renal cell carcinomas that distinction would be difficult if the source were not known. The stroma is composed of thin fibrinous connective tissue bands containing a moderate number of connective tissue cells and relatively few blood vessels. Their bands surround small and large groups of cell, producing a pseudoglandular effect. This effect is further emphasized by the position of the nuclei as mentioned above. Occasionally a true single layered alveolus is seen. No oxyphil or chief cells are found. There are no mitoses."

---

[16] Irregular surfaces with pseudopod-like projections from the parathyroid glands have been recorded (Castleman and Mallory,[18] Cope[20]), but in this instance connection between the glands could be demonstrated only with the left superior parathyroid.

[17] Getzowa, Sophia: Ueber die Glandula parathyreoidea, intrathyreoideale Zellhauben derselben und Reste des postbranchialen Körpers, Virchows Arch. f. path. Anat. **188**: 181-235, 1907.

In addition to the constancy of the large clear cell throughout all glands, the polarity of the nucleus was the next most constant feature. In the vast majority of the cells the nucleus occupied a position in the end of the cell nearest the stroma. A few cells had pink-staining granules within the cytoplasm. The diameter of the cells varied from 10 to 30 microns, with an average of 20 microns. Hyperplasia was self evident. The connective stroma was for the most part sparse, but in a few regions it was abundant. Glandular grouping was very commonly seen. At times the cells were grouped in cordlike formation, and cysts of various sizes were frequent. Adipose connective tissue cells were absent. Blood vessels were numerous. There was some variation in staining between the cells in a single gland and between those in other glands.

There were bronchitis and bronchopneumonia in the lower lobe of the right lung. A few deposits of calcium were present within the alveolar septums.

In the liver a moderate degree of central atrophy with necrosis was present. Bile canaliculi were dilated and filled to an unusual degree with bile thrombi.

In the pancreas, in an occasional duct, there was squamatization, while others had slightly distended lumens. There were focal hydropic changes in numerous groups of acinar cells.

In the duodenum the ulcers were active and penetrated onto the head of the pancreas.

All sections of the kidneys revealed numerous deposits of calcium in the epithelial cells and in the lumen of the tubules (fig. 7). In some regions the deposits of calcium had produced necrosis of the tubular cells. In an occasional glomerulus there was slight proliferation of the cells of Bowman's capsule, while a rare glomerulus was partially or completely fibrosed. There was dilatation of the tubules in a few regions. Numerous small "adenomas" were present in both kidneys.

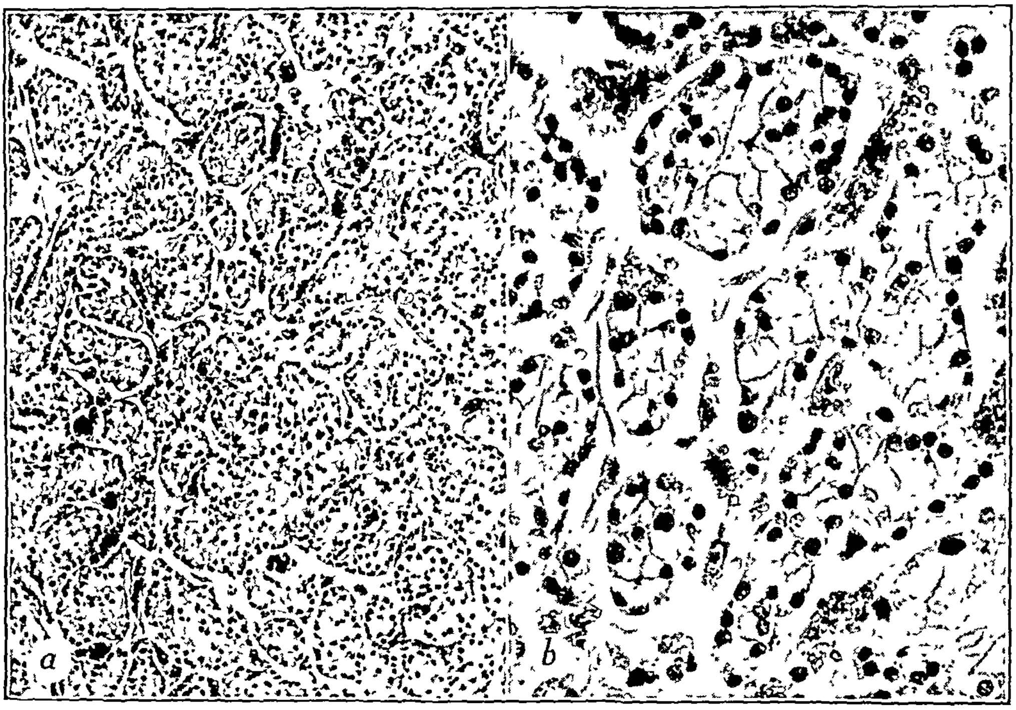

Fig. 8 (case 2).—*a*, hyperplasia of the parathyroids showing large clear cells in pseudoglandular grouping; the polarity of the nuclei is well illustrated (× 120). *b*, large cell hyperplasia of the parathyroids (× 350).

In decalcified microscopic sections of the vertebrae, sternum and ribs the trabeculae were thinned but no cysts or osteoblastic activity was seen.

COMMENT

In the first of these 2 cases of probable acute hyperparathyroidism with coexisting duodenal ulcer the condition was due to an adenoma of the parathyroid gland, composed of chief cells, and there was metastatic calcification in the kidneys, lungs and small arteries. In the second case the condition was due to generalized hypertrophy of the parathyroids and of supernumerary parathyroid glands with hyperplasia of the large, clear cell type. Metastatic calcification was found in the kidneys and the dura mater. The number of supernumerary parathyroids is unusual, and the total amount of parathyroid tissue present in this case showed hypertrophy and hyperplasia to an extreme degree. These 2 cases illustrate well the pathologic changes of the parathyroid gland in hyperparathyroidism. In a review by Castleman and Mallory[18] two distinct changes were emphasized. There may be enlargement of a single gland or adenoma of a parathyroid gland. The adenoma is composed of chief cells or any combination of chief cells with oxyphil cells or large clear cells. Secondly there may be hypertrophy of four parathyroid glands. The significance of primary hypertrophy was first emphasized by Albright and his associates[19] and recently by Cope.[20] In this type of primary hypertrophy and hyperplasia of the parathyroids there is a consistent histologic picture; the cells are all of large clear cell type (wasserhelle). The second case in this report is the first recorded case of primary hypertrophy from the Mayo Clinic.

[19] Albright, Fuller; Bloomberg, Esther; Castleman, Benjamin, and Churchill, E. D.: Hyperparathyroidism Due to Diffuse Hyperplasia of All Parathyroid Glands Rather than Adenoma of One: Clinical Studies on 3 Such Cases, Arch. Int. Med. 54: 315-329 (Sept.) 1934.

[20] Cope, Oliver: Hyperparathyroidism: The Significance of Generalized Hyperplasia: Report of the Seventh Case, Clinics 1: 1168-1178 (Feb.) 1943.

Attention is called to changes of a nonspecific nature present in both cases. In the liver there was atrophy of the central zones. The bile canaliculi were distended to an unusual degree with bile thrombi. Bronchopneumonia was present as a terminal factor.

A portion of the kidney was analyzed for calcium in each case. It was found to contain 0.743 mg. per gram of wet tissue and 4.334 mg. per gram of dry tissue in case 1 and 0.899 mg. per gram of wet tissue and 4.174 mg. per gram of dry tissue in case 2. For control a normal kidney was examined by chemical methods and found to contain 0.0579 mg. per gram of wet tissue and 0.24 mg. per gram of dry tissue.

The existence of hyperparathyroidism in these cases might be questioned in view of the absence of confirmatory laboratory work. However, the findings at necropsy of parathyroid enlargement, the history, the renal changes and the metastatic calcifications are unequivocal. Castleman and Mallory[18] have stated that rigid proof of hyperparathyroidism is often lacking, but in cases of pronounced parathyroid enlargement the burden of proof rests on the disclaimer. That hyperparathyroidism may produce renal lesions in the absence of osseous changes is well known. The osseous changes are thought to be an indication of the duration and degree of the disease as well as of the dietary habits; so that it is probable that osteitis fibrosa cystica is dependent on calcium balance.[21]

The gastrointestinal manifestations of hyperparathyroidism are not as well known as are the osseous and renal changes. Gutman and his associates[22] described anorexia, nausea and vomiting, constipation and epigastric pain occurring in cases of hyperparathyroidism and stated that, "while these symptoms may suggest the diagnosis of duodenal ulcer or acute appendicitis, they have been considered as due to the toxic manifestations of hyperparathyroidism."

The coexistence of duodenal ulcer with hyperparathyroidism presents some interesting problems in regard both to differential diagnosis and to treatment. The diagnosis is complicated by the fact that hyperparathyroidism and duodenal ulcer present many symptoms that are common to the two diseases and their coexistence may obscure the diagnosis. Gutman and his associates have stated that hyperparathyroidism may itself produce symptoms that resemble those of duodenal ulcer. As seen from the cases presented, duodenal ulcers may actually exist with hyperparathyroidism. This coexistence has not been noted previously. When hyperparathyroidism and duodenal ulcers exist together, vomiting may be the manifestation of either one. However, if intractable vomiting occurs with duodenal ulcer in the absence of demonstrable gastric retention, it might suggest the presence of hypercalcemia and in turn hyperparathyroidism. This diagnosis is even more suggestive if the vomiting is aggravated by the institution or the continuation of an ulcer regimen with a diet high in calcium and phosphorus. Anorexia, when present, is in favor of hyperparathyroidism. The occurrence of muscular weakness and lethargy is secondary to the effects of hypercalcemia and, when associated with vomiting, may offer assistance in the diagnosis of hyperparathyroidism. In the 2 cases the presenting symptoms were those of duodenal ulcer, but in retrospect the vomiting aggravated by diet and medication with associated weakness and lethargy was probably the result of hypercalcemia. With coexisting hyperparathyroidism and duodenal ulcer in a patient whose principal complaints seem to be due to a duodenal ulcer, the cause is inevitably and irretrievably lost if the physician is not lucky enough to think of hyperparathyroidism.

The treatment of duodenal ulcer, if complicated by hyperparathyroidism, offers many difficulties. The reverse also is true. The danger of a high calcium intake in cases of hyperparathyroidism was suggested by Hunter and Aub[23] and the greater danger of high phosphorus intake was brought out by Albright, Bauer, Claflin and Cockrill.[24] Albright[1] now recommends a diet with a low calcium intake in cases of severe hyperparathyroidism and states that "if the serum calcium is near the critical level where a slight increase in it would precipitate parathyroid poisoning it may so happen that a diet high in calcium would make the difference." In the cases reported, the prescribed diet contained a daily calcium intake of 1.87 Gm. and a daily phosphorus intake of 1.56 Gm. This, compared with the daily calcium requirement of 0.80 Gm. as recommended by the National Research Council, and the average phosphorus intake of 1.40 Gm. of the adult male,[25] is greater than normal. An additional source of calcium and phosphorus intake to be considered is the medication. The standard Sippy powder contains calcium carbonate. Other drugs used in the treatment of duodenal ulcer, such as tribasic calcium phosphate, may add to the intake of these minerals. It is conceivable that such a diet might easily aggravate preexisting hyperparathyroidism with the production of parathyroid poisoning. Furthermore, medication may further aggravate the condition, and any medication that produces an alkaline urine may favor the precipitation of calcium phosphate in the renal tubules in cases of hyperparathyroidism.

SUMMARY

In neither of 2 cases of probable acute hyperparathyroidism not recognized during life did the history suggest osseous or renal disease. The presenting symptoms in each were those of coexisting duodenal ulcer and probable hypercalcemia. Treatment for duodenal ulcer, including a diet high in calcium and phosphorus, produced in each instance an exacerbation of symptoms: nausea, vomiting, lethargy, prostration and azotemia.

In the first case acute hyperparathyroidism was due to an adenoma of the parathyroid gland. In the second case it was associated with primary wasserhelle hyperplasia of the parathyroids and of supernumerary parathyroids. The latter case is the first reported instance of primary hyperplasia of the parathyroid glands from the Mayo Clinic. Metastatic calcification was present in the kidneys in both cases and involved the lungs and arterioles in case 1 and the dura mater and lungs in case 2.

FOREIGN BODY (CASE KNIFE) IN THE SIGMOID

ARKELL M VAUGHN, M D
Chicago
and
JAMES A MARTIN, M D
Pittsburgh

Foreign bodies in the sigmoid are rather infrequent, while foreign bodies in the rectum are reported more often Foreign bodies in the rectum are usually inserted accidentally, at other times inserted as prankish debauches Frequently sexual perverts stimulate this erogenous zone with various foreign bodies, which occasionally slip up into the rectum beyond their grasp This was the circumstance in the case presented

Various types and assortment of solid foreign bodies in the rectum have been reported Sharon[1] reports the removal of a tall mustard or pickle jar, 14 cm in height and 17 5 cm in circumference, from the rectum of a man aged 54 Clark[2] removed a thermometer accidentally lost in the rectum of a boy baby aged 11 months Hubrich[3] removed a woman's hairpin lying crosswise in the rectal ampulla in a boy aged 13 years The hairpin had been inserted in the rectum a month previously Hubrich stated that "thought should be given to the possibility of a foreign body in treating all cases of chronic constipation" Alley[4] removed a 30 watt frosted glass electric light bulb from the rectum of a grandfather aged 52 with, as he expressed it, "only slight damage to the patient" Chisholm[5] reported an unusual foreign body in the rectum and sigmoid in the form of an "iron rod approximately ½ inch in diameter which was bent upon itself in its upper half to form a handle Its overall length was 13½ inches and the handle portion, which was uppermost in the bowel, was 2¾ inches wide The object is technically known as a 'tuck pointer' and is used by masons in smoothing the mortar between rows of brick" This object was removed by laparotomy, an opening being made in the descending colon, with uneventful convalescence

Rosser[6] mentioned five examples of foreign bodies removed by him, namely (1) a five cent piece, swallowed five years previously, from a young woman with a congenital vaginal anus when he constructed an anal outlet, (2) a thermometer from a 4 year old child, (3) a 6 inch sauce bottle from a young male college student, (4) a 40 watt Mazda electric globe from a man aged 60 and (5) an enema tip

One of us (A M V) removed an enema tip which accidentally became detached while the patient was taking an enema The tip was impinged by lying crosswise in the rectum Under general anesthesia the tip was successfully removed

Meagher[7] reported the removal of a drinking glass 4 inches high, 2⅜ inches across the bottom and 2⅝ inches across the top from the rectum of a sexual pervert

Smiley[8] removed a glass tumbler surgically, resulting in death sixteen hours later

Warren[9] removed a fish hook from a man aged 60 who two days previously had eaten several jellied eels He also considered the possibility of its presence as an extraordinary weapon for use in anal eroticism

Hawe[10] removed surgically with a colostomy a jam jar 2½ inches in diameter at its base and 3 inches high, with recovery.

Hartwig[11] removed a rough irregular stick, 11 inches long from the rectum It presented a tumor mass in the region of the gallbladder and did not penetrate the bowel wall, probably because of the existence of a long mesosigmoid, as was likewise found in our case, in which the tumor mass was to the right of the umbilicus (fig 1)

Glendon[12] removed a jelly glass by surgical laparotomy, with recovery

Gillespie[13] removed a petrolatum bottle and Pretty[14] an ink bottle rectally

Cleghorn[15] removed a 10 inch ice pick by laparotomy, with death on the tenth postoperative day

Ball[16] removed a listerine bottle rectally by a loop made from a wire coat hanger

Macht[17] removed a "seven-up" bottle from an American sailor and stated that until then this was the eighth recorded case in which a bottle was present in the rectum According to Macht, the most remarkable foreign bodies reported in the literature up to 1943 were a snuff box, whisky glasses, a 30 cm mortar pestle, ox horns, electric light bulbs, an ink bottle, petrolatum bottle, cold cream jar, a lemon, an apple, chicken bones, a glass tube, portions of a broom handle, frozen pig's tail, and most unusual of all (cited by Macht) was "a tool box containing a piece of gun barrel, a screw driver, two hack saws, a boring syringe, a file, several coins, thread and tallow The tool box and its contents were removed from a prisoner who made his escape through death from obstipation At autopsy the tool kit was found to have migrated into the transverse colon"

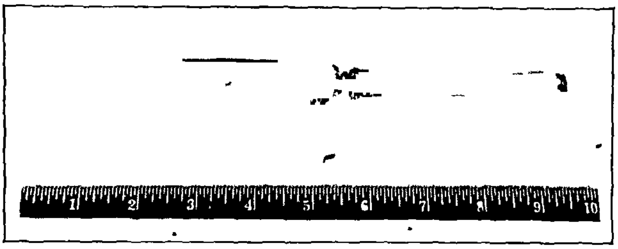

Fig 1 —Nine inch case knife removed from sigmoid colon via rectum The blunt end was pointed cephalad

REPORT OF CASE

V S, a white man aged 25, entered Cook County Hospital, Chicago, at 9 50 p m, Oct, 12, 1944, with an admitting room diagnosis of umbilical hernia His present complaint was pain in the abdomen for eighteen hours

He gave a history that while lifting a packing box weighing 150 pounds (68 Kg) at 3 15 a m, October 12, suddenly everything "let loose" inside his stomach and he immediately was seized with a severe, sharp, "knife like" pain in the region of the umbilicus, causing him to drop the box He returned home by street car and after he had lain in bed for one and one-half hours the pain seemed to disappear for several hours When he got up and attempted to go down stairs the pain returned but again disappeared after lying down for a while He went to his employer to receive his pay check and again the pain returned He consulted the plant physician, who

advised hospitalization. En route to the hospital via street car the pains became so severe that he was compelled to get off the car and sit on the curb. A passing motorist came to his assistance and brought him to the hospital. After lying in bed for a while the pain gradually disappeared.

The history revealed no nausea, vomiting, constipation, diarrhea nor melena past or present. He experienced, however, attacks of "heartburn" following the ingestion of fatty foods as pork and sausage.

On the day of admission he first noticed a small, hard tender "knot" just to the left of the umbilicus.

The family history revealed that his mother and one sister had died of tuberculosis. One living sister had tuberculosis and one living brother had been insane all his life.

The patient had lost 36 pounds (16 Kg.) since being discharged from the Army in September 1943 because of arthritis of the spine and poor eyesight. Eight years before admission he suffered for four months with rheumatism. He stated that he did not have a venereal disease. He said that he drank 1½ gallons of beer daily with a couple of "shots" of whisky and masturbated one or two times daily. He was rather uncommunicative and sullen and offered no information which would have guided us toward a correct diagnosis.

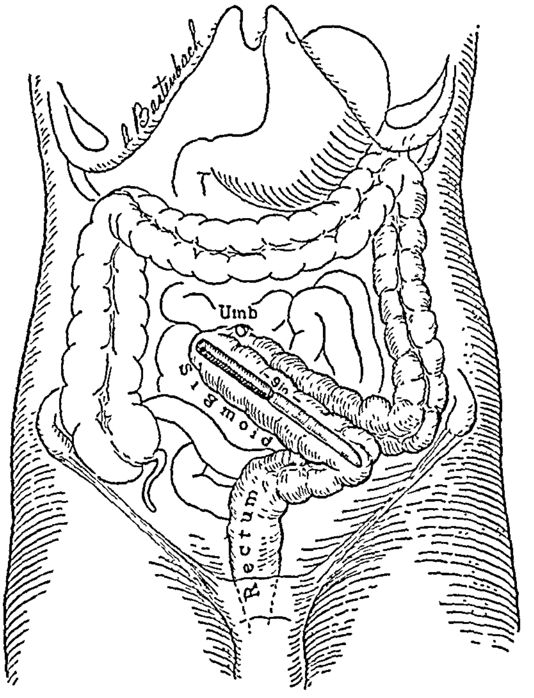

Fig. 2.—Diagrammatic sketch showing position of knife in sigmoid colon. Note the long mesosigmoid, which enabled the knife to assume this position.

On physical examination the patient appeared moderately well developed, listless and in no acute distress. His rectal temperature was 99.8 F., pulse rate 68, respiratory rate 16 and blood pressure 112/65. A systolic heart murmur at the apex was heard and was transmitted over the entire precordium. In the abdomen a small 1 by 1 cm. hard, tender nodule, not hot nor red, was noted to the left of the umbilicus, giving the appearance of a periumbilical hernia. No other masses were palpable. The abdomen was soft. The peristaltic sounds were normal. There was no distention and no inguinal nor femoral hernia present. Rectal examination was negative. No masses were felt as far as the examining finger could reach.

The urine and blood were normal.

The impression was one of (1) umbilical hernia with incarcerated omental tab; (2) rheumatic heart disease, with mitral regurgitation and cardiac enlargement.

The patient was seen and examined by the night surgeon and the night surgical resident on call at 3 a. m., October 13. They did not consider the case a surgical emergency, but advised observation. At 9 a. m. on the same day the surgical resident in the ward (J. A. M.) examined the patient and made the following notations:

"Patient has a small hard, painful, freely movable nodule just to the right of the umbilicus. No obstructive signs or symptoms: I believe this to be a rectus sheath herniation. Should be explored in the next few days."

A progress note on October 14 stated "Hard knot near umbilicus still present: It is very tender but freely movable over an area of 5-10 cm. square about umbilicus."

The following week the patient had no complaints unless the mass was palpated. The bowel movements were normal on general diet. There was no distention. Rectal examination was negative. Surgical exploration of the tender nodule was advised.

A preoperative diagnosis of umbilical hernia with incarcerated omental tab was made and the patient was operated on under general anesthesia on October 23. A transverse incision was made below and to the right of the umbilicus. The sheath of the rectus abdominis was split about 4 inches at the lateral border and the muscle retracted medially. The mass was found to be intra-abdominal and the peritoneum was cut longitudinally long enough to admit the hand. A long hard mass was found in the lumen of the redundant sigmoid lying obliquely in the lower abdomen to the right of the umbilicus and pointing left toward the middle of the inguinal ligament. The mass was carefully manipulated and milked down the sigmoid into the rectum, where an assistant was able to grasp the tip and with gentle pressure from above and traction below the mass was removed via the rectum and found to be a 9 inch table or case knife (fig. 1).

The abdominal wall incision was closed in layers. The patient made an uneventful recovery and was discharged from the hospital on the eleventh postoperative day.

SUMMARY

Rectal examination will detect foreign bodies in the rectum but may fail to do so when they have ascended into the sigmoid or higher. In this case report rectal examination was negative, owing to the fact that the knife had ascended into the sigmoid and occupied an oblique position in the lower part of the abdomen (fig. 2). Owing to wartime scarcity of x-ray films, when only x-rays of the most urgent cases are ordered, no x-rays were taken. In normal times a scout plate would have been taken and a definite diagnosis obtained.

Surgical removal by laparotomy either by opening the colon or by directing the foreign body downward toward the anus is in many instances necessary. The mortality is greatly increased when the colon is opened, but with the advent of succinylsulfathiazole it is hoped and expected that the rate will be greatly lowered. Laparotomy alone gives a very low mortality.

In reviewing the literature we were unable to find a similar case of foreign body in the sigmoid or rectum.

The irony of this case was the fact that the complaint on admission was a "knife like" pain in the abdomen. How true this proved to be on opening the abdomen eleven days later!

CONCLUSIONS

1. Foreign bodies in the sigmoid may pass unrecognized by rectal examination.
2. A long mesosigmoid may allow the foreign body to ascend high within the abdominal cavity.
3. A foreign body in the sigmoid must be differentiated in cases of freely movable lower abdominal tumors.
4. Fatalities may occur in removing foreign bodies from the sigmoid surgically.
5. A history is not always realiable, especially in patients by whom the foreign body was used as an instrument of sexual perversion.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

BACTERIAL VACCINE MADE FROM HEMOPHILUS PERTUSSIS.—Pertussis vaccine.—Whooping cough vaccine.—A sterile suspension of killed pertussis bacilli (Hemophilus pertussis) of one or more strains showing the characteristics of phase I as described by Leslie and Gardner. The suspension is contained in isotonic solution of sodium chloride or other suitable diluent. The vaccine may be dispensed as a simple suspension, commonly known as "plain vaccine," or as an alum precipitated or aluminum hydroxide adsorbed suspension. The vaccine shall contain in each cubic centimeter not less than 10 billion organisms. The vaccine may be dispensed by itself or in combination with one or more other antigens, provided the combination does not lessen the antigenic value of the pertussis vaccine or otherwise make the product unsuitable for human use.

Actions and Uses.—Well controlled field studies indicate that pertussis vaccine possesses sufficient antigenic value to afford considerable protective value against whooping cough. The effect in lowering the death rate is even more striking than its effect in preventing an attack of the disease, since cases do occur in spite of the previous injection of vaccine, but such cases are usually less severe.

Dosage.—The most satisfactory dose has not been established adequately. In general, the vaccine when used as a plain vaccine should contain not less than 15 billion organisms per individual injection, with the total dose representing at least 45 billion, preferably much more. When used as precipitated vaccine the individual injection should contain not less than 10 billion organisms, with a total dose of 30 billion or more organisms. Pending more complete knowledge it is suggested that the user be guided by the dosage recommendation given on the manufacturer's product, since this represents the dosage accepted by the investigators whose methods have been used in preparing the vaccine.

CUTTER LABORATORIES, BERKELEY, CALIF.

Pertussis Vaccine Phase I Concentrate: 5 cc., 20 cc. and 50 cc. vials. H. pertussis 20,000 million per cubic centimeter. Preserved with phenol 0.25 per cent and merthiolate 0.002 to 0.005 per cent.

THE NATIONAL DRUG COMPANY, PHILADELPHIA

Pertussis Vaccine (Double Strength): 6 cc. vial (one immunization), 12 cc. vial (two immunizations) and 25 cc. vial (four immunizations). H. pertussis 20,000 million per cubic centimeter. Preserved with merthiolate 1 : 10,000.

SHARP & DOHME, INC., GLENOLDEN, PA.

Pertussis Bacterin "H" Strength: 5 cc. and 20 cc. vials. 20,000 million H. pertussis per cubic centimeter. Preserved with phenol 0.5 per cent.

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Pertussis Vaccine (Single Strength): 24 cc. vials. 20,000 million H. pertussis per cubic centimeter. Preserved with phenol 0.5 per cent.

Pertussis Vaccine (Double Strength): 5 cc. and 20 cc. vials. 20,000 million H. pertussis per cubic centimeter. Preserved with phenol 0.5 per cent.

PERTUSSIS VACCINE ALUM PRECIPITATED.—A bacterial vaccine prepared from alum precipitated, killed H. pertussis.

Actions and Uses.—Same as Bacterial Vaccine made from H. pertussis.

Dosage.—Three 1 cc. subcutaneous injections of 10,000 million or 15,000 million H. pertussis at three to four week intervals.

THE NATIONAL DRUG COMPANY, PHILADELPHIA

Pertussis Vaccine (Alum Precipitated): 3 cc. vial (one immunization) and 10 cc. vial (three immunizations). 10,000 million H. pertussis per cubic centimeter. Preserved with merthiolate 1 : 10,000.

PERTUSSIS VACCINE COMBINED WITH DIPHTHERIA TOXOID.—A combination of pertussis vaccine with diphtheria toxoid.

Actions and Uses.—Employed in the simultaneous immunization of susceptible persons against diphtheria and whooping cough.

Dosage.—Three doses of 1 cc. at three to four week intervals.

THE NATIONAL DRUG COMPANY, PHILADELPHIA

Diphtheria-Pertussis Combined Vaccine (Alum Precipitated): Three 1 cc. vials (one immunization) and three 5 cc. vials (five immunizations). 10,000 million H. pertussis, 0.5 cc. diphtheria toxoid immunizing dose. Preserved with merthiolate 1 : 10,000.

SHARP & DOHME, INC., GLENOLDEN, PA.

Diphtheria-Pertussis Antigens Combined (Alum Precipitated): 10 cc. vials (three dose immunizations). 10,000 million H. pertussis diphtheria toxoid immunizing dose. Preserved with phenol 1 : 50,000.

PERTUSSIS VACCINE COMBINED WITH DIPHTHERIA AND TETANUS TOXOIDS.—A combination of pertussis vaccine with diphtheria toxoid and tetanus toxoids.

Actions and Uses.—Employed in the simultaneous immunization of susceptible persons against whooping cough and diphtheria.

Dosage.—Three subcutaneous injections of 1 cc. at three to four week intervals.

THE NATIONAL DRUG COMPANY, PHILADELPHIA

Diphtheria-Tetanus-Pertussis Combined Vaccine (Alum Precipitated): Three 1 cc. vials (one immunization) and three 5 cc. vials (five immunizations). 10,000 million H. pertussis, diphtheria toxoid and tetanus toxoid 0.33 cc. each per cubic centimeter. Preserved with merthiolate 1 : 10,000.

CONTRACEPTIVE JELLIES AND CREAMS (See New and Nonofficial Remedies, 1945, p. 355).

The following article has now been accepted:

EATON LABORATORIES, INC., NORWICH, N. Y.

Lorophyn Jelly: A water soluble jelly formed from tragacanth and purified Irish moss, having a p_H of 7.5, prepared from the formula:

	Per Cent
Phenylmercuric acetate	0.05
Polyethylene glycol of mono iso octyl phenyl ether	0.3
Gum tragacanth	1.8
Purified Irish moss	2.0
Glycerin	8.0
Methyl p-hydroxy benzoate	0.05
Sodium borate U. S. P.	3.0
Water	84.8

Actions and Uses.—See article Contraceptive Jellies and Creams.

Dosage.—5 cc.

SYRINGE APPLICATORS FOR CONTRACEPTIVE JELLIES AND CREAMS (See New and Nonofficial Remedies, 1945, p. 357).

The following article has now been accepted:

EATON LABORATORIES, INC., NORWICH, N. Y.

Lorophyn Jelly Applicator: A transparent plastic syringe threaded at the blunt, intravaginal end, to screw onto the tubes of jelly, to permit filling by compression of the tube. The full capacity is 5 cc., the recommended dose.

HEXAVITAMIN (See THE JOURNAL, Aug. 11, 1945, p. 1099).

The following dosage form has been accepted:

THE WM. S. MERRELL CO., CINCINNATI

Tablets Hexavitamin: Each tablet contains 2,500 U. S. P. units of vitamin A, 200 U. S. P. units of vitamin D, 1 mg. of thiamine hydrochloride, 1.5 mg. of riboflavin, 37 mg. of ascorbic acid and 10 mg. of nicotinamide.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1945, p. 428).

The following dosage forms have been accepted:

BRISTOL LABORATORIES, SYRACUSE, N. Y.

Diethylstilbestrol (in Sesame Oil): 0.2 mg. per cc.; 0.5 mg. per cc.; 1.0 mg. per cc.; 2.0 mg. per cc. and 5.0 mg. per cc.: 1 cc. ampuls and 30 cc. vials. Preserved with 0.005 Gm. chlorobutanol.

MEDICAL APPOINTMENTS IN THE VETERANS ADMINISTRATION

Announcement of the appointments of consultants to veterans' hospitals, including members of the faculties of the leading medical schools which are cooperating with the Veterans Administration, has aroused anxiety among physicians still in the armed forces as to the possibility that all the available places may be filled before their release from the service. THE JOURNAL is informed by the administrators of the Veterans Administration that not all the places have been filled by any means and that there will be opportunities for practically all the well qualified men who wish to serve for several years to come. In areas not associated with medical schools, appointments will be made directly from Washington.

Recently THE JOURNAL published an announcement from the Surgeon General of the U. S. Public Health Service indicating that many positions are vacant in that organization. The Army Medical Department has available many positions for physicians who have been in the service, and the Navy is currently determining how many of its reserve officers will accept permanent appointments.

Elsewhere in this issue appear two statements relative to the Veterans Administration which should be read carefully by all who are interested in taking part in this work. The Veterans Administration is especially anxious to secure the services of physicians with neuropsychiatric training or who may be especially interested in neuropsychiatry and willing to take graduate study in this field. The legislation establishing a division of medicine in the Veterans Administration has been passed by the House and the Senate and will no doubt be signed by the President. An analysis of the legislation published in this issue of THE JOURNAL indicates the opportunities available both in full time and in consultant capacities. Applications may be made directly to the Veterans Administration in Washington, D. C.

PRECURSORS OF THE PORPHYRINS

The question of the identity of chemical substances used in the formation of the porphyrins in the body has been a matter of speculation for many years. The problem is important in medicine because a number of respiratory pigments, including hemoglobin, the cytochromes and catalase, contain the porphyrin group. Furthermore, it is conceivable that an impairment of porphyrin formation might be responsible for some clinical anemias and that a derangement of normal porphyrin formation may occur in such clinical conditions as congenital porphyria and other types of porphyrinuria in man. Thus an understanding of the manner in which porphyrin is formed in the organism becomes of practical importance.

From the classic chemical studies of Hans Fischer,[1] a Nobel laureate, it has been found that porphyrins may be synthesized in vitro from rather simple starting materials such as aminoacetic acid and formyl acetone. Also the fact that the porphyrins contain four pyrrole rings suggests that one or more amino acids, perhaps including proline, are probably involved in porphyrin synthesis in vivo. Evidence that this is the case has been reported in a recent paper[2] indicating that the excretion of porphyrin in the feces of rats is diminished in animals fed a diet low in protein. An anemia develops concomitantly. If porphyrin excretion is an index to porphyrin synthesis under these conditions, it follows that porphyrins are synthesized in the rat from amino acids derived from dietary protein.

Substantiation and extension of this observation have been reported[3] in direct studies on a human subject using the isotope tracer technic. The subject was given aminoacetic acid which contained isotopic nitrogen. Blood samples were withdrawn at intervals for ninety-nine days, and the porphyrin derivative hemin was crystallized and analyzed for isotopic nitrogen content. A relatively high value was obtained, thus demonstrating the participation of aminoacetic acid in the synthesis of porphyrin in the human subject.

Using a similar technic in rats, the Columbia University investigators found that neither leucine[4] nor ammonia[5] was directly concerned with porphyrin synthesis, whereas acetic acid[6] (fed as deuterio acetate) was used for this purpose, since it appeared in the isolated hemin crystals.

The foregoing observations thus indicate that the porphyrins are synthesized in the organism from relatively simple chemical substances, including aminoacetic acid and possibly acetic acid. These observations afford another example of "the wisdom of the body" in forming an essential biologic substance from simple, plentiful chemical units. The studies also suggest the improbability that clinical anemias in man may result from an inadequate porphyrin synthesis.

HEALTH PRACTICE INDEXES

The Committee on Administrative Practice of the American Public Health Association offers the health administrator through its "Health Practice Indices" an opportunity to check his work against prevailing practices in the same area of administration.[1] Throughout its evaluation procedures the American Public Health Association has measured performance against the best existing practices rather than against theoretical ideals.

This index volume permits the health officer to check his own department in eighteen principal administrative areas. There are eighty items in the index, and for each there is a chart. Two hundred and forty-three communities in eighteen states reported their activities.

These health practice indexes have been extremely useful. Perhaps the most striking use of them is by the health department of the city of Racine, which in its 1944 report published these indexes in black with a red bar indicating the position of the city in each chart. Thus the citizens were given a complete and wholly frank evaluation of the work of public health agencies in their community.

Among the two hundred and forty-three communities in eighteen states evaluated in these indexes some of the fundamentals of public health service have not yet been developed to their full efficiency. Approved water supplies serving 100 per cent of the people are available in less than 25 per cent of communities of between 1,000 and 2,500 population; the median is 90 per cent served, but some communities run as low as 20 per cent and a few serve none. With respect to sewage disposal the record is similar but not as favorable. Rural school children are being served with water supplies of doubtful safety in a large number of communities. The median figure representing population served with satisfactory drinking water is near 75 per cent, and the lower one fourth of the communities reporting had 50 per cent or less. The same situation exists with respect to disposal of excreta. Vaccination against smallpox among children under 5 years of age indicates that the median is only 18 per cent, and below this the percentage fades rapidly to zero. Actually only two communities exceed 70 per cent, and most of the upper quartile ranges between 60 and 30 per cent of preschool children immunized against smallpox.

Current Comment

COMPLICATIONS FOLLOWING ANTIRABIC TREATMENT

Human rabies is invariably fatal. The period of incubation is from thirty to sixty days and by vaccination effective immunity can be created in a shorter time. The practice is to begin preventive vaccination as soon as possible after bite by a rabid or suspected animal. Casals[1] summarizes the results of this method of prevention during the past fifteen years. The death rate from rabies in more than 1,000,000 cases throughout the world analyzed by McKendrick[2] was 0.33 per cent. This figure does not give the exact value of antirabic vaccination of human beings because the facts as to exposures are not well enough known. In most of the cases exposure to rabies was unproved or doubtful. It is noteworthy that treatment begun as late as fourteen days after exposure appears to have given as good results as that begun earlier. The incidence of complications has been low. Reactions at sites of inoculations are of minor significance. Peripheral neuritis and dorsolumbar myelitis usually end in recovery. The most severe complications are of paralytic nature, often of ascending type. McKendrick lists 181 paralytic complications in 1,060,832 treatments, of which 48 were fatal. This kind of complication occurred more frequently with vaccine of attenuated virus (Pasteur vaccine) than with virus inactivated with phenol (Semple vaccine) or with heat. As it has not been demonstrated that any one of these vaccines is definitely superior to the others, only vaccines of inactivated virus should be used to prevent rabies in human beings, as the risk of dangerous complications will be smaller.

THE G. I. BILL OF RIGHTS

Changes in the G. I. Bill of Rights were effected by legislation passed by the Congress just before the recess. Some are of particular interest to former medical officers who have applied or who will apply for the benefits of the federal law. The requirement in the original law that a veteran over 25 years of age at the time of entry into service must show that his education was interrupted by service in order to be entitled to education benefits beyond the one year period was eliminated. The time within which a course must be initiated was extended from two to four years and the time within which education or training may be afforded from seven to nine years after the termination of the war. The subsistence allowance for a veteran without dependents was increased from $50 to $65 a month and for a veteran with dependents from $75 to $90 a month. The benefits of the titles relating to education and loans were made available to veterans on terminal leave with the exception that subsistence allowances are not payable during that period. This particular amendment was made effective as of June 22, 1944, the date of enactment of the original law. In the case of short, intensive postgraduate or training courses of less than thirty weeks, payment of the reasonable cost therefor was authorized but there will be charged against the veteran's period of eligibility the proportion of an ordinary school year which the cost bears to $500. Not in excess of $500 may be paid for any such course. As an example, if a short course of four weeks costs $250, the entire amount can be paid and the veteran will have utilized one-half a year of his period of eligibility. Heretofore the cost of such a short course has been paid on a pro rata basis. Another amendment, after continuing the limitation of $500 on the amount that may be paid to an institution on behalf of a veteran during an ordinary school year, provides that the veteran may elect to have the customary charges of the institution paid in excess of the limitation, in which event there will be charged against his period of eligibility the proportion of an ordinary school year which such excess bears to $500. This amendment permits a veteran to elect to foreshorten his period of eligibility by having paid for him the costs of an educational course in excess of the normal $500 limitation. The loan provisions of the original act were amended in numerous respects in an effort to simplify procedures, but now, as heretofore, the initial loans must be negotiated with a lending agency. Loans are not made by the Veterans Administration.

THE EMPIRICAL FORMULA OF BETA-LACTOGLOBULIN

Proteins are built up of many amino acid units characterized by their complex structures. In addition to the large number of units there exists an astronomically large possible number of arrangements of the amino acids in the straight chain peptide. The complete analysis or synthesis of a protein therefore becomes an extremely difficult task. With the advent of the microbiologic methods of analysis, new tools for the determination of amino acids are made available. These methods require smaller samples, are highly specific and are comparatively rapid. Using some of the orthodox chemical methods in conjunction with microbiologic methods, Brand and his co-workers[1] have determined the complete empirical formula of a pure protein, beta-lactoglobulin. The lactoglobulin unit consists of 370 amino acid residues, with 366 peptide linkages. In addition, it was found that the constituent amino acids are connected by the typical peptide linkage and that other methods of combination, such as ester, anhydride or imide, if present at all, could exist only in extremely small numbers. The determination of the empirical formula of a protein in this manner is an achievement; it has led closer to the solution of many of the fundamental problems in protein chemistry such as digestibility, immunologic specificity and the seat of activity in the protein hormones and enzymes.

THE RELATION OF INFANTILE PARALYSIS TO EPIZOOTIC AVIAN PARALYSIS

The first epidemic of infantile paralysis in Argentina was apparently in 1895. A good many outbreaks have taken place there since then. In the epidemic of 1942-1943 most cases developed in November, December and January. A recent monograph by Rillo and Lagrotta[1] presents a summary of views concerning this disease. The full account in the monograph of Preioni's observations and theories on the relations of infantile paralysis to paralytic epizootics in chickens and other birds raises the question whether a new source and a new method of natural transmission of the virus have been found. The simultaneous occurrence of paralytic disease in poultry and infantile paralysis has been recorded by several observers, but no one seems to have studied fowl paralysis in relation to the human disease so extensively and with such far reaching application as Preioni.[2] The paralytic fowl epizootic is described by him as corresponding closely to infantile paralysis in both clinical manifestations and nervous lesions; that is, the basic process is an acute anterior poliomyelitis. He assumes that in birds the infection is transmitted by the bite of a chicken louse (Dysmanisium avis) and that birds may be vehicles as well as victims of lice. The louse may be conveyed also by adhering to the surface of eggs and is of course widely distributed in poultry yards and houses. The louse is said to bite human beings, mostly on the legs. As it feeds on the blood and lymph of poultry and other birds, such as sparrows, it may by its bite transfer to human beings virus and other infectious agents from infected birds. In fact, this is the way in which infantile paralysis is spread, according to Preioni's theory. It is assumed that the virus enters through the bite of the skin and passes by perineural lymphatics to the central nervous system, the particular lesions and symptoms depending largely on the location of the bite. The immediate reaction about the bite is not described in detail but referred to as a local lymphangitis. According to the presentation in the monograph,[1] Preioni's conception is supported mainly by the similarity of the lesions in the anterior spinal horns and the spinal ganglions in the poultry paralysis studied by him and in infantile paralysis. That the poultry paralysis "always precedes and accompanies" infantile paralysis is not established by the facts at hand. So far experimental results do not appear to have been obtained bearing on the relation of fowl paralysis to infantile paralysis. Moreover inoculations of monkeys may be needed to show whether fowl epizootics are caused by the virus of infantile paralysis and also whether the incriminated louse can carry the virus.

MEDICINE AND THE WAR

ARMY

ARMY AWARDS AND COMMENDATIONS

Capt. Arthur B. Coltman

The Military Merit Medal was recently awarded to Capt. Arthur B. Coltman, formerly of Philadelphia. The citation accompanying the award mentioned with considerable detail his service to the Philippine Commonwealth and the Army of the Philippines. "During the period from Dec. 26, 1944 to Jan. 24, 1945, while serving as Philippine Civil Affairs Medical Officer, he organized dispensaries and hospitals, instituted sanitary control measures and by his painstaking and unselfish efforts rendered very valuable medical service to the civilian population of Leyte. On Jan. 29, 1945 he participated in an amphibious landing on Luzon and aided considerably in securing indispensably needed hospitals, dispensaries, medical relief supplies and food for the use of the war devastated civilians of the province of Zambales. On arriving in Manila on Feb. 23, 1945, regardless of his personal safety, he proceeded to form nineteen medical installations in various sections of the city; with the aid of civilian doctors and nurses these hospitals provided shelter, food, medical attention and life-saving surgical procedures for thousands of civilian battle casualties daily. During June and July of 1945, while he was serving with the Manila Department of Public Health, his sincere and untiring efforts were successfully directed at the problems of immunizing the civilian population of Manila against cholera, typhoid and dysentery, thereby helping considerably in averting the outbreak of an epidemic of this war torn city. From July 28, 1945 to Oct. 10, 1945 Captain Coltman, serving with the Medical Liaison Section of the United States Army Training Group, contributed immeasurably to the training of Philippine Army medical personnel." Dr. Coltman graduated from Hahnemann Medical College and Hospital, Philadelphia, in 1943 and entered the service Jan. 14, 1944.

Major General Robert H. Mills

Major Gen. Robert H. Mills, director of the dental division of the Office of the Surgeon General, was recently awarded the Distinguished Service Medal, which was presented by Major General Norman T. Kirk for "his performance of exceptionally meritorious service in a position of great responsibility." The citation recalled that "with exceptional foresight, organizing ability and leadership he provided and maintained a superior dental service, based on sound plans and professional policies, for the millions in the Army. Under his guidance the Army Dental Corps was expanded from several hundred to more than fifteen thousand officers, and dental facilities, including clinics and laboratories, were expanded proportionately. The dental rehabilitation of more than a million men accomplished under his supervision represented a tremendous contribution to the conservation of fighting manpower and to the future health of the nation. He skilfully coordinated the activities of the Dental Corps with other federal agencies and the civilian dental profession. Through his unremitting efforts to achieve exceptional standards of dental care General Mills made a notable contribution to the war effort." The award was presented at the beginning of a two day conference of service command dental surgeons which was under the direction of General Mills.

Lieutenant Colonel George F. Evans

The Legion of Merit was recently awarded to Lieut. Col. George F. Evans, formerly of Clarksburg, W. Va. Accompanying the award was a citation "for exceptionally meritorious conduct in the performance of outstanding services in North Africa and Italy from Jan. 27, 1943 to May 8, 1945. As chief of medical service in the 29th Station Hospital in North Africa and later in a similar capacity with the 32d Station Hospital in Italy, Lieutenant Colonal Evans through his superior performance of duty contributed materially to the medical service of both hospitals. Regardless of personal sacrifice, he spent many extra hours in organizing and developing his department, instructing the younger officers in the records. His tactful dealing with all ranks and his ability to work under pressure set a high example for other members of his organization. His superior professional abilities and outstanding devotion to duty reflect great credit on Lieutenant Colonel Evans and the Army Medical Service." Dr. Evans graduated from McGill University Faculty of Medicine, Montreal, in 1923 and entered the service Aug. 25, 1942.

Captain Herbert L. Songer

Capt. Herbert L. Songer, formerly of Lincoln, Kan., was recently awarded the Silver Star for gallantry in action, the Bronze Star for meritorious achievement, the Oak Leaf Cluster to the Bronze Star and the Purple Heart when he was wounded in action. The awarding of the Bronze Star was "for meritorious achievement in connection with military operations against the enemy in the European Theater of Operations from Aug. 21, 1944 to Dec. 2, 1944. The professional skill, loyalty and courage with which Captain Songer executed his responsibilities as battalion surgeon contributed immeasurably to the health of his organization's personnel and to the prompt and efficient treatment of battle casualties during the invasion of western Europe." Dr. Songer graduated from the University of Kansas School of Medicine, Kansas City, in 1938 and entered the service Nov. 1, 1942.

Colonel William W. McCaw

The Legion of Merit was recently awarded to Col. William W. McCaw, formerly of Washington, D. C., for his work as department surgeon since March 1944. The citation accompanying the award emphasized his "exceptionally meritorious conduct in the performance of outstanding services during the period March 18, 1944 to Sept. 2, 1945." Colonel McCaw, it continued, "as Alaskan department surgeon, was responsible for supervision of all elements of the medical service in this theater. Health and sanitation of the command, training of troops in military sanitation and first aid, location and operation of hospitals and other medical establishments and of the evacuation service, and supervision of training of medical troops are all functions which came directly under his supervision. By his initiative and untiring devotion to duty the efficiency in accomplishing his mission has earned commendation in all his assignments. His intelligence, industry and devotion to duty are exemplified by the high standard of medical care achieved in this department. His professional ability, judgment and understanding of the problems peculiar to Alaska and the Aleutian Islands contributed much to the health of this command and reflects great credit on himself and on the military service." Dr. McCaw graduated from the University of Pittsburgh School of Medicine in 1916 and entered the service Oct. 29, 1917.

Colonel Sydney L. Stevens

Col. Sydney L. Stevens, formerly of Indianapolis, was recently awarded the Bronze Star for meritorious achievement in connection with military operations. The official citation accompanying the award stated that "during the movement of his division he directed the treatment of the wounded and sick with outstanding efficiency." Dr. Stevens graduated from Indiana University School of Medicine, Indianapolis, in 1937 and entered the service Jan. 10, 1941.

Lieutenant Colonel Harwell Wilson

The Legion of Merit was recently awarded to Lieut. Col. Harwell Wilson, formerly of Memphis, Tenn. The citation accompanying the award read, in part, "The first sixty day period of the hospital's operations in Italy, Lieut. Col. Wilson's surgical service section treated nearly 4,000 cases, most of which were combat casualties from American and French colonial armies. Through unceasing and highly conscientious labor, and by virtue of his outstanding skill as a surgeon, marked devotion to duty and high qualities of leadership, surgical care of the highest order was afforded to thousands of patients, and an exceptionally low death rate was maintained." Dr. Wilson graduated from Vanderbilt University School of Medicine, Nashville, Tenn., in 1932 and entered the service July 15, 1942.

Major David Borak

Major David Borak, formerly of New York, was recently awarded the Bronze Star for "outstanding medical work in the field with Chinese forces." Dr. Borak graduated from the Faculty of Medicine of the University of Vienna in 1937 and entered the service Oct. 10, 1942.

Major Albert M. Betcher

The Bronze Star was recently awarded to Major Albert M. Betcher, formerly of Long Beach, N. Y., "for meritorious service in connection with military operations, as anesthetist, 15th General Hospital, from Sept. 24, 1944 to May 8, 1945. Major Betcher efficiently set up and coordinated the operating room section of the hospital. While coordinating heavy operating schedules and supervising administering of anesthesia, he taught two week courses in anesthesia for medical officers and nurses. By his superior professional skill and devotion to duty, Major Betcher has saved the lives and hastened the recovery of many wounded." Dr. Betcher graduated from St. Louis University School of Medicine in 1935 and entered the service March 10, 1941.

VETERANS

THE NEUROPSYCHIATRIC PROGRAM

[Note.—Following is an appeal from Major General Paul R. Hawley, acting surgeon general, Veterans Administration, to physicians interested in neuropsychiatry.—Ed.]

The Neuropsychiatric Service of the Veterans Administration has positions available to doctors of varying degrees of training and experience. There are openings in general and neuropsychiatric hospitals, in outpatient clinics, in administrative positions in branch offices, and in the central office in Washington, D. C.

The Office of Postgraduate Instruction and Research is meeting success in obtaining the cooperation of medical colleges to further the teaching program in hospitals. The doctor entering the Veterans Administration can be assured that graduate training will be available, designed toward qualification for the American Board of Psychiatry and Neurology, if such is his or her desire.

Our thirty-three neuropsychiatric hospitals have acute, semiacute, chronic and semipermanently invalided patients. There are urgent psychotic patients in need of immediate treatment, those who have endured severe situational illness in the armed forces in various stages of recovery, and outpatients for follow-up study, in addition to the more chronic groups. In this rich assortment of clinical material, opportunities will be available for all types of study and treatment.

In fifty-one general hospitals an active neuropsychiatric service is being created as well. The emphasis in these units will be on active treatment of cases with good prognosis, and an attempt will be made whenever possible to complete treatment at the general hospital level. In such installations an opportunity for a concentrated experience in therapy as well as diagnosis will be afforded the members of the staff.

Another feature of general hospitals is the readjustment center for patients with neuroses. It is planned to establish such centers in hospitals as quickly as possible. Doctors working in these units will have opportunity to use all forms of therapy used in the armed services on acute neuroses, as well as some of the more prolonged technics—group therapy and brief psychotherapy in various forms.

Those physicians interested primarily in neurology, and all psychiatrists who wish to obtain experience in this field, will find opportunities to extend their studies in this direction. Plans call for an increase in our activities in neurology throughout our hospitals. As a part of this, a training program is projected in electroencephalography for both doctors and technicians in the near future.

Mental hygiene clinics will be established in thirty-one of the larger cities of the country. Positions will be available here for full time or part time clinical work. These installations will afford the clinician the satisfying experience of preventing disabling neurosis in many of his cases, plus the equal satisfaction of seeing to it that the more serious cases are hospitalized in an early stage when therapy will be of greatest benefit.

Financial remuneration for full time work in the Veterans Administration begins in Civil Service grade P & S-3 at a salary of $3,640 per annum and is graduated up to P & S-8 at a salary of $9,800 per annum. Many openings are available at P & S-4 ($4,300 per annum) and P & S-5 ($5,180 per annum). For those who wish to inquire into higher administrative positions, these will be available in grade P & S-6 ($6,230 per annum) and grade P & S-7 ($7,175 per annum). All pay schedules listed are basic and provide retirement benefits. In a bill already passed by the Congress to establish a medical department in the Veterans Administration, a 25 per cent increase is contemplated for all physician qualified by specialty boards.

Those who are interested in a career in the Neuropsychiatric Service of the Veterans Administration should make application to Dr. Daniel Blain, Acting Director, Neuropsychiatric Service, Veterans Administration, Washington 25, D. C., stating a preference as to type and location of installation preferred and enclosing a short summary of civilian and military training, experience and qualifications. Positions are available for part time consultants as well, and inquiry concerning them can be addressed in the same manner, or through Deans' Committees of affiliated medical schools.

Interested physicians are cordially invited to come to the central office in Washington, D. C., for personal interview with Dr. Blain's staff. It is preferable that this be done by appointment.

For those interested in training in neuropsychiatry per se, the Veterans Administration is planning to augment the facilities now available throughout the country. One such training center has been established and is in operation in Topeka, Kan., under the direction of Dr. Karl Menninger. Short refresher courses are available as well as a three year comprehensive training course in neurology and psychiatry, designed toward rendering its students eligible for examination by the National Board of Psychiatry and Neurology. Information concerning this school can be obtained by direct inquiry to Dr. Karl Menninger, Veterans Administration Hospital, Topeka, Kan. Opportunities for training will soon be available in several other locations.

Although much of what has been said is applicable to medicine in general in the Veterans Administration, I have addressed myself to America's neuropsychiatrists specifically because of our great need for your cooperation in our program. The physicians in this specialty in our organization are sorely overtaxed, and they need your assistance. On your willingness to lend them a hand depends the future success of their program for the returned veteran.

VETERANS' RESEARCH AIDE

Major William T. Doran, Bronxville, N. Y., was recently appointed assistant director of postgraduate instruction and research of the Veterans Administration. Major Doran recently returned from duty with the Medical Corps of India and China. He will assist Dr. Paul Magnuson in organizing postgraduate instruction in Veterans Administration hospitals.

ORGANIZATION SECTION

Medical Legislation

DEPARTMENT OF MEDICINE AND SURGERY IN THE VETERANS ADMINISTRATION

An Analysis of H. R. 4717 Prepared by the Bureau of Legal Medicine and Legislation, American Medical Association

Congressional action has been completed on H. R. 4717, a bill to create in the Veterans Administration a Department of Medicine and Surgery. While he disclaimed perfection for the legislation and frankly recognized that it contained objectionable provisions, the Acting Surgeon General of the Veterans Administration, Major Gen. Paul R. Hawley, urged that Senate action on the bill be not delayed in an effort to remove those provisions. He stated before the Senate Committee on Finance that unless action on the bill was completed before the Christmas recess the medical service of the Veterans Administration would "suffer further grave consequences which may well be irreparable. In the interest of the thousands of disabled veterans who have, by their sacrifices, earned better medical care than they are now receiving, I urge immediate action upon this bill." Responding to this plea, the Senate passed the bill without amendment.

In the opinion of the Senate Committee on Finance, legislation to make available a better quality of medical care for veterans should (1) incorporate adequate provisions as to organization and authority without military aspects; (2) provide by statute certain positions with adequate salary stipulations, with specified salary ranges for physicians, nurses and dentists, and a special salary range for attendants; (3) authorize appointments to certain specified positions without regard to civil service, by the Administrator of Veterans' Affairs; (4) provide a civil service system of retirement in preference to a military system; (5) retain classified civil service for positions not specifically exempted therefrom by the legislation; (6) incorporate authority to dispense with the services of unsatisfactory or disqualified employees in certain categories without the restrictions of the laws and regulations pertaining to civil service, and (7) incorporate such special provisions as are necessary to insure an adequate and complete medical and hospital service in the Veterans Administration. H. R. 4717, as viewed by the committee, will meet these objectives.

THE DEPARTMENT OF MEDICINE AND SURGERY

The new department will include an Office of the Chief Medical Director, Medical Service, Dental Service, Nursing Service and Auxiliary Service. The Chief and Deputy Medical Directors must be qualified doctors of medicine and will be paid a salary of $12,000 and $11,500 a year, respectively. Provision is made for the appointment of eight Assistant Medical Directors, one of whom will be a qualified doctor of dental surgery and will be directly responsible to the Chief Medical Director for the operation of the Dental Service. Each such Assistant Medical Director will be paid a salary of $11,000 a year. There will be a Director and Deputy Director of Nursing Service at a salary of $8,000 and $7,000 a year respectively. A Chief Pharmacist, Chief Dietitian, Chief Physical Therapist and a Chief Occupational Therapist will each be paid a salary of $6,000 a year. All of these appointments will be made by the Administrator of Veterans' Affairs for a four year period, and reappointments may be made for successive like periods. The administrator may remove an appointee for cause.

Section 4 authorizes the employment of additional personnel, including doctors, dentists, nurses, managers of hospitals, homes and centers, pharmacists, physical therapists, occupational therapists, dietitians, pathologists, bacteriologists, chemists, biostatisticians and other medical and dental technologists.

QUALIFICATIONS FOR APPOINTMENT

A person to be eligible for appointment to the Department of Medicine and Surgery must be a citizen of the United States. For appointment in the Medical Service, the appointee must hold the degree of doctor of medicine or of doctor of osteopathy from a college or university approved by the Administrator, have completed an internship satisfactory to the Administrator and be licensed to practice medicine, surgery or osteopathy in one of the states or territories of the United States or in the District of Columbia. Similar qualifications are included to apply to appointments in the Dental Service, in the Nursing Service and in the Auxiliary Service. Persons on terminal leave from the armed forces may be appointed and may be paid for their services rendered under such appointment notwithstanding any law or regulation to the contrary.

Appointments of physicians, dentists and nurses will be made only after qualifications have been satisfactorily established in accordance with regulations prescribed by the Administrator and without regard to civil service requirements. Appointments authorized by section 4 will be for a probationary period of three years. The record of each person serving under an appointment in the Medical, Dental and Nursing services will be reviewed from time to time by a board appointed in accordance with regulations by the Administrator. If the board finds any appointee not fully qualified and satisfactory, he will be separated from the service. Physicians, dentists and nurses serving in the present Medical Service will be continued in their present positions until the Administrator shall have determined their qualifications.

PROMOTIONS

Promotions of physicians, dentists and nurses will be made only after examination given in accordance with regulations prescribed by the Administrator. Automatic promotions within grade may be made in increments of the minimum pay of the grade in accordance with the regulations.

PRESERVATION OF CIVIL SERVICE STATUS

The new law provides for the protection of civil service reinstatement rights in cases of those who at the time of appointment have a civil service status and whose employment in the department is not continued.

GRADES AND PAY RANGES

In the Medical Service there will be six grades beginning with the junior grade with a minimum salary of $3,640 and advancing to the chief grade, with a maximum salary of $9,800. In the Dental Service there will be five grades, ranging from the junior grade with a minimum salary of $3,640 to the senior grade with a maximum salary of $8,225. In the Nursing Service there will be four grades, ranging from junior grade with a minimum salary of $2,320 to senior grade with a maximum of $5,180. There is provision, in addition, for an Assistant Director of the Nursing Service with a salary range from $5,180 to $6,020.

The Administrator will be authorized to prescribe by regulation the hours and conditions of employment and leaves of absence of physicians, dentists and nurses.

RATING AS SPECIALISTS

The Chief Medical Director will be authorized to rate any physician appointed under section 4 as a medical or surgical specialist. No such rating may normally be given unless the physician is certified as a specialist by an American specialty board. In event that no such board exists, the rating may be given if the physician has been examined and found qualified by a board appointed by the Chief Medical Director from specialists of the Department of Medicine and Surgery holding ratings in the specialty to which the candidate aspires. In case there are insufficient specialists to constitute such a board, the Chief Medical Director may substitute consultants with comparable qualifications employed on a temporary full time, part time or fee basis.

Physicians to whom such specialist rating is given will hold it until it is withdrawn by the Chief Medical Director after a determination has been reached by a board of specialists that the physician is no longer qualified in this specialty.

Physicians who are given the rating of specialists will be entitled, in addition to their basic pay, to an allowance equal to 25 per cent of such pay, subject to the restriction that the basic pay plus the allowance may not exceed $11,000 a year.

CIVIL SERVICE RETIREMENT BENEFITS

Persons appointed to the Department of Medicine and Surgery will be subject to the provisions of and entitled to benefits under the Civil Service Retirement Act of May 22, 1920.

DISCIPLINARY BOARDS

The Chief Medical Director will be authorized to appoint disciplinary boards to determine, on notice and fair hearing, charges of inaptitude, inefficiency or misconduct. Each board will consist of not less than three nor more than five employees, senior in grade, of the Department of Medicine and Surgery. The Administrator will appoint a chairman and secretary of each board, who will have authority to administer oaths. The Chief Medical Director may appoint one or more investigators to assist in the collection and presentation of evidence, and every person against whom charges are made may be represented at the hearing by counsel of his own choice. A disciplinary board may recommend reprimand, suspension without pay, reduction in grade, and discharge from the Department of Medicine and Surgery. The Administrator will be required either to approve the recommendation as made, approve it with modification or exception, approve it and suspend further action at the time, or disapprove such recommendation; and the decision of the Administrator will be final.

APPOINTMENT OF ADDITIONAL EMPLOYEES

The Administrator will be authorized to appoint, under civil service laws, rules and regulations, such additional employees as may be necessary. Employees of the Medical Service as at present constituted, other than those previously mentioned, will receive original appointments to the department in their present civil service status on certification of satisfactory service by the manager of the hospital, home or center where such person is at present employed. The annual salary range for hospital attendants will be $1,572 minimum to $1,902 maximum.

SPECIAL MEDICAL ADVISORY GROUP

The Administrator will be required to establish a special medical advisory group composed of members of the medical and allied scientific professions, nominated by the Chief Medical Director. The duties of this group will be to advise the Administrator, through the Chief Medical Director, and the Chief Medical Director direct, relative to the care and treatment of disabled veterans and relative to other matters pertinent to the Department of Medicine and Surgery. The group will conduct regular calendar quarterly meetings, and the number, terms of service, compensation and allowances to members of the group will be in accord with existing laws and regulations.

ATTENDANCE AT MEETINGS

The Chief Medical Director will be authorized to detail designated personnel to attend meetings of associations for the promotion of medical and related sciences and to pay their expenses. Among others, the Deputy Medical Director, the eight Assistant Medical Directors and the physicians, dentists and nurses appointed under the authority contained in section 4 may be so designated.

POSTGRADUATE INSTRUCTION

The Administrator will also be authorized to afford educational opportunities to the personnel referred to in the preceding paragraph by detailing them to schools of the Army, Navy and Public Health Service and to civil institutions of learning for the purpose of increasing the professional knowledge or technical training of the personnel of the department. Such details may not be for a period in excess of ninety days in a year, will be subject to the consent of the authorities of the institutions and may not exceed 5 per cent of the personnel of the department at any one time. Tuition, transportation and educational fees of personnel so detailed will be paid. If any person authorized to attend any such course of training voluntarily leaves the service within two years after the completion of the course, he will be required to reimburse the Veterans Administration for the expenses incurred.

EMPLOYMENT ON PART TIME BASIS

On the recommendation of the Chief Medical Director, the Administrator may employ, without regard to the Classification Act of 1923, physicians, dentists and nurses on a temporary full time, part time or fee basis. Dietitians, social workers, librarians and other professional, clerical, technical and unskilled personnel may be employed on a temporary full time or part time basis at such rates of pay as the Administrator may prescribe. No temporary full time appointment may be made for a period in excess of ninety days.

RESIDENCIES

The Administrator will be authorized to establish residencies, to appoint qualified persons to such positions without regard to civil service or classification laws, rules or regulations and may prescribe the conditions of such employment, including necessary training, and the customary amount and terms of pay during the period of such employment and training.

RULES AND REGULATIONS

The Chief Medical Director with the approval of the Administrator, unless specifically otherwise provided, will be authorized to promulgate all regulations necessary to the administration of the Department of Medicine and Surgery and consistent with existing law. Such regulations will include those relating to travel, transportation of household goods and effects, and deductions from pay for quarters and subsistence and to the custody, use and preservation of records, papers and property of the Department of Medicine and Surgery.

EFFECTIVE DATE OF LAW

This law becomes effective from the date of its approval by the President.

MEDICAL BILLS IN CONGRESS

G. I. Bill of Rights

A conference report on H. R. 3749, a bill to amend the G. I. Bill of Rights, has been accepted by the House and Senate. As will appear elsewhere in this issue, this bill increases the subsistence allowance available to veterans who pursue educational or training courses, will make certain benefits available to officers while on terminal leave, will eliminate the 25 year age limitation on presumption of interruption of education, will increase the amount that may be paid by the Veterans Administration in connection with short courses pursued by veterans, will permit a veteran to elect to foreshorten his period of eligibility by having tuition charges in excess of $500 paid and amends in numerous respects the loan provisions of the existing law.

National Science Foundation Act of 1945

Senator Kilgore, West Virginia, for himself and Senator Johnson, Colorado, Senator Pepper, Florida, Senator Fulbright, Arkansas, and Senator Saltonstall, Massachusetts, has introduced, as S. *1720*, a revised bill to promote the progress of science and the useful arts, to secure the national defense and to advance the national health and welfare. It proposes to establish an independent agency in the federal government to be known as the National Science Foundation which will be administered by an administrator appointed by the President by and with the advice and consent of the Senate. The administrator will be required to consult and advise with a National Science Board the members of which will be appointed by the President, by and with the advice and consent of the Senate.

Hospital Construction

H. R. 5014, introduced by Representative Lyndon B. Johnson, Texas, proposes to enact the Federal Hospital Aid Act. It was referred to the House Committee on Banking and Currency and would authorize the Reconstruction Finance Corporation to make loans and grants in amounts not exceeding the total of $500,000,000 to municipalities and nonprofit organizations for the planning, construction, improvement and extension of hospitals and public health centers.

Veterans Administration

The bill providing for the creation of a Department of Medicine and Surgery in the Veterans Administration, H. R. 4717, has passed the Senate without amendment. It therefore retains the provision authorizing the utilization of the services of osteopaths in the treatment of veterans.

H. R. 5041, introduced by Representative Weaver, North Carolina, would authorize the Administrator of Veterans' Affairs to furnish domiciliary care and medical and hospital treatment to individuals who have served without compensation for ninety or more days as members of a selective service system civilian local board.

A bill introduced by Representative Doyle, California, H. R. 5012, proposes to dispense with the requirement that a veteran be unable to pay hospital expenses, in non-service connected cases, as a condition to hospitalization and domiciliary care in Veterans Administration facilities.

The construction of a veterans' hospital in Humboldt County, Calif., is proposed by H. R. 4739, introduced by Representative Lea, California.

Miscellaneous

A bill introduced by Representative Elston, Ohio, H. R. 4706, would authorize the appointment of members of the Navy Nurse Corps as commissioned officers of the Naval Reserve.

Washington Letter

(From a Special Correspondent)

December 23, 1945.

Hearings Are Still Awaited on Truman "Health" Program

Congress has taken a twenty-three day vacation during the Christmas and New Year's holidays but faces stormy weather in the second session of the 79th Congress, which starts January 14. President Truman's compulsory health insurance program is one of a number of measures sponsored by the chief executive which are expected to meet with considerable opposition when they come up for passage. The President has also asked for permanent status for the Fair Employment Practices Committees, authorization of labor fact-finding boards, a full employment act, compulsory military training, a higher statutory minimum wage, unification of the Army, Navy and Air Forces, legislation for domestic control of atomic energy, pay raises and pensions for members of Congress and an act to make the speaker of the House next in succession to the White House, Vice President in line of succession to the White House, instead of the Secretary of State. Mr. Truman has also appealed for rapid admission of refugees from Europe to the United States within quota limits, particularly orphaned children.

New Influenza Vaccine Going to Civilians Next Year

The War Department and the United States Public Health Service reveal that licenses have been granted to manufacturers to make the new anti-influenza vaccine for distribution to the general public. The vaccine, developed by the Army and by pharmaceutical firms during the war, will be available next year to civilians. Definite dates could not be named because of the complexity of the problems of laboratory capacity, manufacture and distribution. More than 5,000,000 doses of the vaccine were administered to soldiers in this country during the 1943-1944 epidemic, with promising results. Supplies were shipped overseas last October to army posts abroad and to military establishments in this country to vaccinate soldiers against influenza in the greatest mass test of a medicine in history. The inoculations are said to protect the average person for three to four months.

Medical Survey Boards Subject to Review Under New G. I. Bill

One feature of the revised G. I. Bill of Rights as recently approved is that Army and Navy review boards are authorized to review findings not only of retiring boards but also of medical survey and disposition boards. Some officers have claimed they were wrongly deprived of disability retirement rights. Under the revised bill thousands of veterans may take advantage of the government's offer of loan guaranties and free education. Dr. Francis J. Brown of the American Council on Education states that by next fall colleges will be swamped with applications for ex-G. I.s who can afford to attend school under the higher living allowance. This is expected to have an appreciable effect on the number of medical students starting or resuming medical studies.

Rat Population Checked for Typhus

The increasing number of rats infesting Washington has resulted in a survey of the District of Columbia rat population for typhus infection, if personnel can be obtained from the U. S. Public Health Service, Dr. D. L. Seckinger, deputy health officer for the District, stated. Already three rats captured in one downtown area have been found to be infected A 12 year old girl was infected with typhus recently but recovered, after being bitten by a rat in the K Street area

Because of shortages of nurses, doctors and facilities, 160 Washingtonians with far advanced cases of tuberculosis are not hospitalized, reports Edward K. Funkhauser, of the District of Columbia Tuberculosis Association. He advocated higher salaries for tuberculosis hospital personnel, declaring that pay in the Capital is less than in Maryland or Virginia

Veterans Administration Seeks More Army Hospitals

Major Gen. Paul R. Hawley, acting Surgeon General of the Veterans Administration, reveals that the agency will be able to use more of the armed forces surplus hospitals. Of sixty declared surplus by the Army and Navy, General Hawley and Veterans Administrator Omar Bradley have accepted only eight. The others were deemed of temporary construction or located too far from medical centers. Hawley reports that the shortage of hospital beds is becoming increasingly serious, resulting more from a lack of personnel rather than a shortage of hospital facilities.

General Bradley has informed a Negro delegation that he will make an effort to end segregation of Negroes by the Veterans Administration. Previously he had told Negroes that the agency must follow local custom.

Discharge Scores Reduced for Army and Navy Doctors

Both the Army and the Navy have cut the discharge scores for medical personnel. Male navy doctors who need 53 points now will be cut to 51 points on January 1 and to 50 on February 2. Navy nurses drop from 32 points to 29 Jan. 1. There was a 5 point cut to 65 for Dental and Veterinary Corps officers and for all Medical Corps officers except specialists. The discharge age will be reduced by three years to 45 for all Medical and Dental Corps officers except plastic surgeons. Discharge provisions for Sanitary Corps and Medical Administration Corps officers, army nurses, physical therapists and dietitians remain unchanged.

Blind Instructors Will Teach Blind War Veterans

The Veterans Administration announces that blind instructors will teach blind veterans in nine special instruction centers under a new policy of its occupational therapy department. The agency's problem with sightless veterans almost entirely concerns veterans of the first world war, of which there are 320 in Veterans Administration hospitals and 185 in its homes. Veterans' hospitals are also making increasing use of sports such as golf and has nineteen golf courses in operation, with six more being installed. It is planned to install nine-hole courses in many of its neuropsychiatric and general medical hospitals.

Committee Recommends Establishment of Mental Health Institute

The House Interstate and Foreign Commerce Committee has recommended the establishment of a $4,500,000 mental health institute at Bethesda, Md., to combat the nation's mental health problem. Informed that more than half the country's hospital beds were occupied by neurotic patients, the committee unanimously supported the bill authorizing the U. S. Public Health Service to spend $10 million a year to combat mental diseases. Representative J. Percy Priest, Democrat of Tennessee, sponsor of the bill, declared that the committee action paved the way for a coordinated program.

Federal Alcohol Clinics Advocated

Federal operation of clinics for alcoholic addicts similar to services provided for narcotic users was advocated by William H. Escaville Jr., president of the Atlas Publishing Company and a leader in Alcoholics Anonymous. Addressing a Rotary Club audience, he appealed for more constructive government and civil action to cope with alcoholism, which he said is a liability to community and family life.

Million Overseas War Veterans Return Monthly

The Senate Mead Investigating Committee was informed by Army and Navy officials that veterans are being returned from overseas at the rate of a million monthly. They also stated there were plenty of ships to bring the troops home. A million men were returned in November and as many more are expected to be brought home this month.

Committee on Scientific Exhibit

THE SAN FRANCISCO SESSION

Section Representatives to the Scientific Exhibit

The various sections of the Scientific Assembly have appointed the following representatives to the Scientific Exhibit to assist and advise in the procurement of exhibits for the San Francisco session, July 1 to 5:

Practice of Medicine
Dr. Thomas C. Garrett, 3803 Oak Road, Germantown, Philadelphia.
Surgery, General and Abdominal
Dr. Warren H. Cole. University of Illinois College of Medicine, 1853 West Polk Street, Chicago 12.
Obstetrics and Gynecology
Dr. Frederick H. Falls, University of Illinois College of Medicine, 1853 West Polk Street, Chicago 12.
Ophthalmology
Dr. Georgiana D. Theobald, 120 Medical Arts Building, Oak Park, Ill.
Laryngology, Otology and Rhinology
Dr. Paul H. Holinger, 700 North Michigan Avenue, Chicago 11.
Pediatrics
Dr. W. Ambrose McGee, 1601 Monument Avenue, Richmond, Va.
Experimental Medicine and Therapeutics
Dr. Robert W. Wilkins, Evans Memorial Hospital, 65 East Newton Street, Boston.
Pathology and Physiology
Dr. Frank W. Konzelmann, Atlantic City Hospital, Atlantic City, N. J.
Nervous and Mental Diseases
Dr. F. P. Moersch, Mayo Clinic, Rochester, Minn.
Dermatology and Syphilology
Dr. Hamilton Montgomery, 102 Second Avenue S.W., Rochester, Minn.
Preventive and Industrial Medicine and Public Health
Dr. Paul A. Davis, 1436 Delia Avenue, Akron 2, Ohio.
Urology
Dr. John H. Morrissey, 40 East Sixty-First Street, New York.
Orthopedic Surgery
Dr. David M. Bosworth, 742 Park Avenue, New York 21.
Gastro-Enterology and Proctology
Dr. Grant H. Laing, 104 South Michigan Avenue, Chicago.
Radiology
Dr. S. W. Donaldson, 326 North Ingalls Street, Ann Arbor, Mich.
Anesthesiology
Dr. Urban H. Eversole, 605 Commonwealth Avenue, Boston.
General Practice
Dr. Wingate M. Johnson, 402 North Liberty Street, Winston-Salem, N. C.

Application blanks for space in the Scientific Exhibit may be obtained from the Section Representatives or from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago 10.

Council on Medical Service and Public Relations

PREPAID MEDICAL CARE NEWS

Prepayment Plans Grow

Delaware: A recent news release by the New Castle Medical Society (Delaware) points out that "one fourth of the people in Delaware are enrolled in the state society's voluntary prepayment medical care plan." A small state, sure, but still an excellent record.

Florida: A prepayment medical service plan will soon be ready to operate in Florida. The preliminary work has been done. The application for a charter gives the name as the Florida Medical Service Corporation. Dr. Leigh F. Robinson of Fort Lauderdale is chairman of the special committee.

Indiana: Indiana approached a step nearer in the development of a prepayment plan at its November 8 house of delegates meeting. The prepayment plan committee was instructed to draft final plans for an indemnity plan and have them ready in December for a special meeting of the state council.

Kansas: Dr. Barrett A. Nelson of Manhattan, president of the Kansas Physicians' Service, has announced that the plan is about ready to start operation. All details have been worked out, and final approval of the state insurance commission is expected soon.

Albany, N. Y.: At present all of New York State is served by prepayment plans except the Albany area. At the Oct. 31, 1945 meeting of the Comitia Minora of the Albany County Medical Society a special committee headed by Dr. J. E. Heslin presented a plan to serve this area. The proposal suggested a combination cash indemnity-service plan to be set up and financed by the eleven counties to be served. Operations would be conducted in cooperation with the Blue Cross plan. Suggested income limits for the service plan were given as $2,000 for the individual, $2,500 for husband and wife and $3,500 for the family. It was further suggested that acceptable monthly rates might be 75 to 80 cents for the subscriber, $1.50 for the subscriber and one dependent and $2 for the family. The plan was approved in principle and referred back to the committee to complete the details of organization.

Community Health Councils

The Community Health Council idea as a medium for public relations and to assist in activating health programs seems to have a promising future. Until recently health councils have generally been local medical society projects. Dr. John Fitzgibbon has emphasized the importance of such councils in the statement that most public health problems could be satisfactorily solved at the local level if local medical societies would assume the leadership in a plan of cooperative effort with other interested local organizations and agencies with whose leaders friendly relations were easily made or already existent.

Another program just instituted, which presents a different and interesting approach to the problem, is that of the Michigan Health Council. This is not an effort solely by the doctors of Michigan but represents the combination and coordination of their influence and support with that of other organizations of the state which have a common interest. The council was incorporated a year ago as a joint organization of the Michigan State Medical Society, the Michigan Hospital Association, Michigan Medical Service and Michigan Hospital Service.

Public Relations

The Louisiana State Medical Society has developed a working system for getting the facts on various health bills to the doctors. The society's congressional committee and other special committees gather the facts and opinions of Congressmen. This is disseminated to the membership through editorials and articles in the *New Orleans Medical and Surgical Journal* along with special detailed reports. An advertising committee arranges for newspaper space throughout the state to get facts to the public, and the medical societies arrange for editorial comment.

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

DISTRICT OF COLUMBIA

Personal.—A hospital now being constructed in Ciudad Trujillo, Dominican Republic, will be named in honor of Dr. William A. Morgan, Washington, in recognition of his services while in that country early this year.

The Davidson Lecture.—Dr. Joseph T. Roberts, adjunct clinical professor of medicine at Georgetown University School of Medicine, Washington, was chosen the Davidson Lecturer of the Medical Society of the District of Columbia in 1945. In the competition to select the lecturer Dr. Roberts submitted a paper on "The Role of the Small Vessels and Nerves of the Heart in Heart Failure and Cardiac Pains."

Faculty Changes at Georgetown.—Dr. Henry R. Schreiber, clinical professor of medicine at Georgetown University School of Medicine, was recently promoted to professor and acting director of the department of medicine, filling the vacancy that occurred with the resignation of Dr. Wallace M. Yater (THE JOURNAL, December 1, p. 970). Dr. William F. O'Donnell was promoted to professor and acting director of the department of pediatrics to succeed Dr. Joseph S. Wall, who resigned after serving as a member of the faculty for forty-seven years. Dr. Charles A. Millwater was named associate professor of clinical pediatrics to succeed Dr. John H. McLeod, resigned.

GEORGIA

Personal.—Dr. Cornelius F. Holton, Savannah, has been appointed chief surgeon of the Central of Georgia Railway, effective September 1, succeeding Dr. Craig Barrow, who died August 31.——Dr. Arthur D. Knott, Leesburg, has been made health officer of Mitchell County with headquarters in Camilla.

Richard Wood Fills New Position.—Dr. Richard Hugh Wood has been appointed associate professor of medicine at Emory University Medical School and physician-in-chief at Emory University Hospital. The position of physician-in-chief is a newly created one and Dr. Wood is the first appointee. Dr. Wood was an associate in medicine prior to entering military service.

Department of Physical Medicine Created.—Emory University on December 21 announced the establishment of a department of physical medicine at its hospital and the start of a five year program in the specialty for Atlanta and the Southeast under a grant of $167,000 from the National Foundation for Infantile Paralysis. The department will be operated by Emory University School of Medicine under the direction of Dr. Robert L. Bennett, director of physical medicine at Georgia Warm Springs Foundation and newly appointed professor of physical medicine on the medical school faculty. Dr. Bennett will divide his time between Warm Springs and Atlanta. Plans also call for appointment of an assistant director in charge of research and a staff to include a resident, two technicians and a secretary. After the first year the staff will be gradually enlarged to reach a total of seven specialists and two secretaries by the end of the five year period. The staff "will investigate various phases of physical therapy and cooperate with other departments in the university medical school in the application of physical medicine to the treatment of patients." The program will provide for extensive research in the field of physical medicine as applied to neuromuscular diseases, particularly poliomyelitis; a schedule of training for doctors in physical medicine and for technicians in physical therapy, and establishment of facilities for the treatment of victims of infantile paralysis and other diseases by physical therapy.

ILLINOIS

Chicago

The Bacon Lectures.—Carl R. Moore, Ph.D., professor and chairman of the department of zoology, University of Chicago, will deliver the Charles Sumner Lectures for 1945-1946 at the University of Illinois College of Medicine January 16-17 on "Studies in the Biology of Sex." Individual titles of the lectures will be "The Role of Sex Hormone in the Differentiation of the Reproductive System" and "Some Aspects of Development in the Uterus, and in Ovaries Subjected to Experimental Treatment."

Meeting of Institute of Medicine.—At the annual meeting of the board of governors of the Institute of Medicine of Chicago, December 12, the following officers were elected for the coming year: Drs. William F. Petersen, chairman of the board of governors; Ernest E. Irons, president; Percival Bailey, vice president; George H. Coleman, secretary; Grant H. Laing, treasurer. Dr. Italo F. Volini was elected a member of the board of governors for a term of five years. At the thirtieth annual meeting of the institute on December 4, in the Grand Ball Room of the Palmer House, Mrs. Harry Hart, long actively engaged in health and child welfare services in Chicago, Miss Mary E. Murphy, the director of the Elizabeth McCormick Memorial Fund, and Mr. Wilfred S. Reynolds, director of the Council of Social Agencies of Chicago, were received into citizen fellowship. Citizen fellowship is conferred by unanimous vote of the board of governors on persons who are interested in and who have materially contributed to the welfare of the community in the field of medicine, dentistry, nursing, public health, social service or instruction, and not more than three candidates can be elected in any one year.

KENTUCKY

Personal.—Layton B. Hardman, D.Sc., LaGrange, has resigned as superintendent of the Mallory Taylor Memorial Hospital.——Dr. Joseph P. Holt, assistant professor in the department of physiology, University of Louisville School of Medicine, has been appointed director of medical research, Standard Oil Company of New Jersey, with offices in New York.——Dr. George M. McClure Jr. has been appointed a member of the Danville Board of Education.

Physician Honored for Public Service.—Dr. Owen M. Carroll, New Castle, was recently presented with the medal for meritorious professional and public service sponsored and donated by Dr. E. Murphy Howard, Harlan, past president of the Kentucky State Medical Association, in recognition of his many services to organized medicine and to his people for more than a half century. Dr. Carroll has served for thirty-seven years as secretary of the Henry County Medical Society and for thirty-eight years as health officer of the county.

Changes in Health Officers.—Dr. George M. Wells, Bowling Green, has returned to the directorship of the Warren and Simpson County health departments, succeeding Dr. Paul Q. Peterson, who has been granted a scholarship in public health at the University of Michigan. Dr. Raymond E. Wehr, Newport, has been named health officer of Campbell County. He has been acting health officer since last September, when he filled the vacancy that occurred with the death of Dr. Clayton W. Shaw, Alexandria. Dr. Frank K. Sewell has been named health officer for the Knox, Whitley and Laurel county health district, succeeding Dr. Richard B. Fulks, Barbourville, who has been granted a fellowship to pursue a course in public health. Dr. Charles D. Cawood, Lexington, has resigned as health officer of the Lexington-Fayette County Health Department. Dr. Wilber V. Bradshaw Jr., Stanford, is the new health officer of Shelby County, succeeding Dr. Bertha A. C. Wiseman.

MASSACHUSETTS

Obstetrical Meeting.—On December 12 the New England Obstetrical and Gynecological Society held its seventeenth annual meeting at the Harvard Club, Boston. In addition to clinics held at the Free Hospital for Women, Carney Hospital and the Boston City Hospital the program included:

Dr. Louis K. Diamond, Boston, The Recent Practical Advances in the Understanding of the Rh Factor.
Dr. Arthur T. Hertig, Boston, Hydatidiform Mole: Some Recent Pathologic and Clinical Observations on Two Hundred Cases.
Dr. Edward G. Waters, Jersey City, N. J., A Discussion of Disputed Indications and Technics for Cesarean Section.

MICHIGAN

Physician Members of Rehabilitation Advisory Committee.—According to a recent announcement, the four physician members of the sixteen member state advisory committee for vocational rehabilitation include:

Dr. Charles L. Hess, Bay City, reappointed, representing Michigan State Medical Society
Dr. Raymond Hussey, Detroit, representing Wayne University.
Dr. William DeKleine, Lansing, representing the state health department.
Dr. Carleton Dean, Lansing, representing the Michigan Crippled Children Commission.

Grant for Research.—The Smith, Kline and French Laboratories have made a grant of $2,500 a year for two years to Dr. Amedeo S. Marrazzi, professor and head of the department of pharmacology and therapeutics of Wayne University

College of Medicine, Detroit. The grant is for the further study, by electrical methods, of drugs acting on the autonomic and central nervous systems.

MINNESOTA

Gift for History in Public Health.—The Minnesota Historical Society has announced the receipt of a gift of $25,000 from the Mayo Properties Association, Rochester, for the writing and publication of a history of public health in Minnesota.

Grant for Medical Fellowships.—A gift of $25,000 was made to the University of Minnesota Medical School, Minneapolis, by the Ebin Foundation of Minneapolis to support five graduate medical fellowships of $1,000 a year each, to be awarded immediately to veterans of World War II.

The Bell Lecture.—Dr. Haven Emerson, New York, acting director of the Minnesota School of Public Health, Minneapolis, gave the twelfth annual Bell Lecture before the Hennepin County Medical Society, December 3. His subject was "What Public Health Expects of the Private Physician."

Carl Potthoff Joins Red Cross.—Dr. Carl J. Potthoff, associate professor of preventive medicine and public health, division of personal health and health education, University of Minnesota Medical School, Minneapolis, has resigned to become assistant medical director of the American Red Cross with headquarters in Washington, D. C., according to the *Bulletin of the Hennepin County Medical Society.*

Personal.—Dr. Lewis S. Jordan, Granite Falls, was elected president of the Minnesota Public Health Association recently to succeed Dr. Francis E. Harrington, Minneapolis.——Dr. Jay Arthur Myers, professor of preventive medicine and public health, division of public health administration and epidemiology, University of Minnesota Medical School, Minneapolis, has been elected editor-in-chief of the *Journal of the American College of Chest Physicians.*

Electron Microscope.—An electron microscope has recently been installed in Millard Hall at the University of Minnesota Medical School, Minneapolis. The following are among the investigations which will involve the use of the microscope: the intracellular identification of a virus-like agent responsible for the high percentage of mammary carcinoma in susceptible strains of mice, microscopic examination of bone, dentin and enamel, a study of the nature of virus inclusions in certain diseases such as vaccinia and herpes, and studies of the finer detail of bacteria with diameters of the order of 0.5 micron.

Proposed Heart Hospital.—The Variety Club of the Northwest has offered to sponsor the construction of a hospital on the medical campus of the University of Minnesota Medical School, Minneapolis, to be known as the Variety Heart Club of the Northwest. A movement has already started to provide for a $325,000 structure on the medical campus. Sponsored by the Variety Club of the Northwest, it will be financed by all northwestern residents who are interested in the advancement of public health. The Variety Club will pledge a minimum of $25,000 a year to the institution for the care of children from counties that do not have funds available for such care. The unit will comprise a hundred beds. A hundred bed hospital, completely equipped with the most modern of accommodations and equipment to treat patients with rheumatic disease, will also be a clinic available for doctors throughout the Northwest to study this disease. It will also be an outpatient clinic in which ambulatory patients from the entire Northwest can be examined and obtain diagnosis. The research facilities at the University of Minnesota will provide cooperation of all phases of medical science. In this heart hospital it will be possible to study not only rheumatic fever in children but also all phases of heart disease in adults.

NEW YORK

Graduate Lectures.—Dr. David J. Impastato, New York, will discuss "The Value of Shock Therapy in Psychiatry" before the Nassau County Medical Society in Rockville Center, January 29. Dr. John G. F. Hiss, Syracuse, will discuss "Rheumatic Fever—Rheumatic Heart Disease" before the Ontario County Medical Society January 8 in Canandaigua. The first lecture is sponsored by the state medical society and the second by the society in cooperation with the state department of health.

Human Death from Rabies.—On October 17 a 2½ year old girl died in Buffalo from rabies. She had received medical treatment within one hour of the time she had been bitten on September 22 while playing in the yard of her home in Concord. A moderately deep laceration on the right side of the nose medial to the lower eyelid was cauterized with fuming nitric acid and the wound closed with a single suture, according to *Health News.* A superficial "scratch" beneath this injury and wounds of the mouth which apparently were not lacerated or bleeding were not cauterized. Antirabies vaccine was not given. On October 13, twenty-one days after the bite, the child had onset of illness with fever and vomiting. The following day she was removed to a hospital in Buffalo. She died October 17. Tissue from the brain removed at necropsy showed the presence of typical Negri bodies.

Foundation and Hospital Set Up for Rheumatic Fever.—A hospital for the care and treatment of children and other minors suffering from rheumatic fever and rheumatic heart disease has been established in Syracuse as the nucleus of the recently incorporated Rheumatic Fever Foundation of Onondaga County. The new hospital, a composite medical center, home, school and church, on November 6 had 12 patients; its total capacity is 40. According to *Health News,* the foundation was incorporated October 26. Its objectives include:

> To establish and maintain a hospital and a dispensary for the treatment of children and minors suffering, or suspected to be suffering, from rheumatic fever and rheumatic heart disease and their complications, and a coordinated clinic for the follow-up care and study of discharged hospital patients.
>
> To establish and maintain for research purposes a laboratory for the study of the causes of rheumatic fever and rheumatic heart disease and their treatment
>
> To cooperate with other established agencies and institutions, both public and private, interested in the prevention, detection and treatment of rheumatic fever and its complications

The work of the foundation is being administered under the supervision of seven directors, two of whom are physicians: Dr. John G. F. Hiss, Dr. Brewster C. Doust and Messrs. Frederick K. Kilian, William A. Barry, Arthur G. Lyons, Carl A. Bubie and Richard F. Harrison.

New York City

Cancer Committee Names Executive Director to Expand Activities.—Mr. Savel Zimand has resigned as director of the bureau of health education of the city department of health to become executive director of the New York City Cancer Committee. In his new position Mr. Zimand will direct the committee's proposed program of expansion, which will include education of the public with regard to the prevention, early diagnosis and treatment of cancer, informing the public where such services can be secured and promoting the establishment of more adequate facilities.

Physician Chosen "Outstanding Citizen."—Dr. Thomas H. Curtin, chairman of the Bronx Inter-Faith Council, was honored November 28 at a meeting of the Bronx Rotary, Lions and Kiwanis clubs at the Concourse Plaza Hotel. Dr. Curtin had been selected by fourteen Bronx civic and professional organizations as the "outstanding citizen" of the Bronx in 1945. Dr. Curtin, who came to the Bronx in 1900 as coroner's physician and later helped to found the Bronx Eye and Ear Infirmary, received a plaque for his civic, philanthropic and professional activities. He also received a citation from the Inter-Faith Council.

OHIO

Changes in Health Officers.—Dr. Robert A. Evans, Columbus, resigned as temporary health officer of Franklin County December 1. He has held the position for three years. Dr. Homer L. Mitchell, health commissioner, has now returned from service in the army.

Dwight Palmer in Charge of New Department.—Dr. Dwight Palmer, associate professor of neurology and psychiatry, Ohio State University College of Medicine, Columbus, has been made professor and chairman of a newly created department of neurology and psychiatry, it was announced December 3. Dr. Palmer has been a member of the staff of the university since 1927.

Neuropsychiatric Institute Organized.—The Neuropsychiatric Institute of Cleveland was recently organized at 10528 Park Lane, Cleveland 6. The project was started by a number of psychiatrists who felt that adequate psychiatric care could be given in a teamwork arrangement that included psychologists and such laboratory facilities as electroencephalography. Likewise, the institute was set up to give ambulatory electrocoma (shock) treatment. Organized by the staff, the institute is self supporting. Seminars in neuropsychiatry have been established for physicians of the Veterans Administration in the region and for local practicing physicians. Dr. Joseph L. Fetterman is director and Dr. Maurice D. Friedman associate director.

OKLAHOMA

Executive Secretary Takes Over Postgraduate Work.—With the resignation of Mr. L. W. Kibler as field director of the postgraduate course conducted by the postgraduate committee of the Oklahoma State Medical Association, Mr. Dick Graham, formerly executive secretary, has assumed the duties, and the course will continue under his direction.

Wann Langston New Dean at Oklahoma.—Dr. Wann Langston, professor and chairman of the department of medicine and for more than thirty years affiliated with the University of Oklahoma School of Medicine, Oklahoma City, has been appointed acting dean of the school, filling the vacancy that occurred with the death of Dr. Tom Lowry, December 11. Dr. Langston graduated at the University of Oklahoma School of Medicine in 1916. He was medical superintendent of the University Hospital from 1923 to 1926, becoming on Jan. 1, 1927 superintendent, a position he held for about a year, when he went into private practice.

TEXAS

Chairman of Anatomy Named.—Donald Duncan, Ph.D., professor of anatomy at Louisiana State University School of Medicine, New Orleans, has been appointed professor and chairman of the department of anatomy at the University of Texas Medical Branch, Galveston, effective February 1.

GENERAL

New Secretary for Industrial Nurses.—Miss Elizabeth Andrews, R.N., has been named executive secretary of the American Association of Industrial Nurses, effective January 1, succeeding Mrs. Gladys L. Dundore, R.N., resigned.

Society News.—The fifth International Assembly of the International College of Surgeons will be held at Lima, Peru, March 25-27 in the Hospital Obrero under the general chairmanship of Dr. Francisco Graña. Those in the United States desiring to present papers should address Dr. Albert A. Berg, 10 East 73d Street, New York. General information may be obtained from Dr. Max Thorek, Secretary General of the College, 850 Irving Park Road, Chicago 13.——The American Gastroenterological Association will hold its annual meeting at the Hotel Claridge, Atlantic City, May 24-25. Dr. Jacob Arnold Bargen, Rochester, Minn., is secretary.——The seventeenth annual convention of the Aero Medical Association of the United States will be held at the Edgewater Beach Hotel, Chicago, April 7-9.——The American College of Physicians will hold its annual meeting in Philadelphia May 13-17 with headquarters at the Philadelphia Municipal Auditorium.

Seminar for Specialists in Allergy.—The American Academy of Allergy announces its seminar for specialists in allergy on January 7-11 under the joint auspices of the American Academy of Allergy and the New York Postgraduate Medical School. Among the speakers will be:

Dr. Albert Vander Veer, New York, Hay Fever.
Dr. Sanford B. Hooker, Boston, Chemistry of Antibody and Antigen.
Dr. Russell C. Grove, New York, Sinusitis in the Diagnosis and Treatment of Allergic Diseases.
Dr. Paul Klemperer, New York, Pathologic-Anatomic Aspects of Allergy.
Dr. Samuel M. Feinberg, Chicago, The Importance of Molds in Allergic Conditions.
Dr. McKeen Cattell, New York, Pharmacology of Drugs Used in Allergic Conditions.
Dr. Horace S. Baldwin, New York, The Importance of Differential Diagnosis in the Practice of Allergy.
Dr. Frances Pascher, Brooklyn, The Treatment of Allergic Dermatosis.
Dr. Joseph Harkavy, New York, Vascular Allergy.
Dr. Robert A. Cooke, New York, The Antibodies Concerned in Skin Sensitive Allergies.

Lasker Award Goes to Psychiatrists.—The Lasker Award was conferred jointly November 1 on Dr. John R. Rees, consultant in psychiatry to the directorate of psychiatry of the British army, and Major Gen. George Brock Chisholm, deputy minister of national health, federal department of national health and welfare of Canada. The presentation was made by Gen. Omar N. Bradley, administrator of veterans' affairs, at the annual luncheon meeting of the National Committee for Mental Hygiene. The Lasker Award of $1,000, established in 1944 by the Albert and Mary Lasker Foundation, is given annually through the committee for meritorious service and significant contributions to promoting mental health and increasing public understanding of mental hygiene. Each year the award is made for distinguished service in some special aspect of the field of mental hygiene which is of current significance, the honor going in 1945 for service in the field of rehabilitation. The recipient of the award is chosen by members of a jury anonymous to one another as well as the general public, selected annually for competence to judge accomplishment in a particular field. The National Committee for Mental Hygiene reelected its officers at the recent meeting.

International Association of Allergists.—Dr. Fred W. Wittich, secretary-treasurer, American College of Allergists, announces that, after planning and study by representative officers of various existing national allergy societies in different countries, the International Association of Allergists has been incorporated. Pan American and Pan European sections will be affiliations of the association. It is planned to hold the first international congress in Paris in 1948, when universal standards of terminology and classification of allergies will be adopted. Preliminary to this program it is proposed that the same subjects will be the theme of the first Pan American Congress to be held under the auspices of the American College of Allergists at its next annual meeting, tentatively set for Oakland, Calif., June 28-30. The members of the first executive committee, which will compose the temporary group of officers until the election in 1948, are Drs. Karl Figley, Toledo, Ohio; Jonathan Forman, Columbus, Ohio; Guido Ruiz-Moreno, Buenos Aires, Argentina; Abelardo Saenz, Montevideo, Uruguay; Pasteur Vallery-Radot, Paris, France, and Dr. Wittich, chairman, Minneapolis. Executive offices and headquarters of the new association have been set up adjoining the offices of the college. The address is 401 La Salle Medical Building, Minneapolis 2.

Government Services

Consultant Named for Veterans Administration

A group of thirteen consultants has been appointed to the staff of the Veterans Administration Hospital, Hines, Ill. The new appointees are drawn mainly from the faculties of the medical schools at Northwestern University and the University of Illinois as well as from officer personnel being separated from the medical corps of the army. The appointment of these consultants are a phase of the program of Major Gen. Paul R. Hawley, acting surgeon general, Veterans Administration, and Dr. Paul B. Magnuson, Chicago, newly appointed director of postgraduate instruction and research. The names of the physicians are Lindon Seed, Oak Park, Ill., Harold C. Lueth and Richard H. Young, both of Evanston, Ill., Frederick C. Hoebel, River Forest, Ill., and John Martin, Edwin M. Miller, John H. Mohardt, Frederick W. Fitz, Earle I. Greene, Robert M. Jones, Charles B. Puestow, Mitchell A. Spellberg and Everett L. Strohl, all of Chicago.

New Medical Classification for the Library of Congress and the Army Medical Library

Based on studies for new alternative schedules for medicine, class R, and for the preclinical sciences in class Q for the Library of Congress System, a new classification will soon be put into effect. The Army Medical Library plans an early classification of its collection under the new schedule. Because its is expected that alterations, additions and subtractions will be found necessary, it is judged wise not to make the provisional first draft of the classification available for general distribution. The process of classifying the Army Medical Library collection should result in establishing the system in permanent form. It will then be possible to publish it as an integral part of the Library of Congress classification schedules. It should be noted that the notation for these new schedules has been planned so that it will not conflict with the use of those in the original Library of Congress scheme for class Q and class R. The material from these classes has been assigned to heretofore unused portions of the alphabet, the new Q divisions occupying QS to QZ, while medicine proper (the former R sections) utilizes the wholly vacant letter W. This will make it possible for libraries already using the present Library of Congress classification for medicine and related sciences to continue to do so or, if they prefer, to apply the new system, leaving their previous collections as they are. The Library of Congress will announce its policy with respect to use of the new schedules before they are published. Keyes D. Metcalf, Litt.D., is chairman of the committee on a new medical classification for the Library of Congress and the Army Medical Library. Miss Mary L. Marshall is responsible for the actual work on the new classification under a committee representing the Harvard College Library, the Library of Congress and the Army Medical Library survey committee.

Rehabilitation of Patients with Head Injuries

The immense experience with head injuries during the war has advanced knowledge of the subject. Much work has been done at the Military Hospital for Head Injuries at St. Hugh's, Oxford. During the past eighteen months the Nuffield Provinsional Hospitals Trust, the Ministry of Pensions and the Radcliffe Infirmary, Oxford, have been considering some plan for dealing with the after-treatment of head injuries. As a result of modern neurosurgery and chemotherapy, men with brain wounds who formerly would have died have survived. Many have regained speech, sight and mental faculties; paralyzed limbs have recovered. These results have been achieved through courage and perseverance by the patients, a favorable environment and the guidance of a skilled team of workers. But recovery is often incomplete, and frequently severe permanent disability remains. Inability to cope with ordinary conditions of civilian life and the fear of being a drag on their families cause anxiety, disappointment and frustration.

If these men are to make their contribution to the community within the limitations imposed by their disabilities, it is necessary to assess their physical, mental and vocational capacity for work while they are in the hospital. Later they must be given facilities for simple training in various forms of work more advanced and more satisfying to the desire to be useful than occupational therapy alone can afford. Finally for the gravely disabled a permanent center must be provided which will give medical care with apropriate forms of useful work. These men can live with their families around the center whose protection they need.

The following steps are now being taken to deal with the problem: The Ministry of Pensions recognizes that head injury patients comprise a group for which special provision must be made and that further research on the best methods of rehabilitation is necessary. For this research the Radcliffe Infirmary, Oxford, with the aid of a donation of $100,000 from the Nuffield Provincial Hospitals Trust, has appointed Dr. W. Ritchie Russell. Before the war he was lecturer in neurology at Edinburgh University and during the war worked at the Military Hospital for Head Injuries, Oxford. He will work in close collaboration with the departments of Oxford University, already engaged in the study of lesions of the nervous system. He will give specialized assistance and advice to the Ministry of Pensions. By these means the latest methods of treatment will be made available to pensioners.

The Health Conditions of European Countries

An encouraging picture of health in Europe has been drawn by Dr. George Stuart, head of the Medical Information Branch of the United Nations Relief and Rehabilitation Administration. Although present conditions favor epidemic diseases, the situation is not nearly so dangerous as after the last war. Smallpox is negligible; typhus has been almost eliminated from Europe west of the Elbe-Adriatic line. In several western countries and especially in Germany there is a high incidence of diphtheria, typhoid and dysentery, largely the result of malnutrition in overcrowded and ruined areas. Typhoid is the most dangerous disease in Europe, reaching in September thirty times its normal incidence in Germany. Tuberculosis has also increased, especially in Italy, Yugoslavia and Greece, where its frequency is ten times as great as in Britain. Twenty years of venereal disease control has been nullified during the war, for there is a three to nine fold increase of syphilis in most European countries, and up to a twenty fold increase in Germany. Malaria is of epidemic proportions only in Greece, but it is hoped that modern methods of control can almost eradicate it there in two or three seasons.

UNRRA is doing great work to combat these diseases. Medical supplies are now flowing into all the countries with which the organization is concerned, although transport difficulties often delay distribution. From Britain alone 60,000 hospital beds, with all the necessary equipment, have been sent. By the end of September UNRRA had shipped over 11,000 tons of medical supplies into Europe.

ITALY

(From Our Regular Correspondent)

Naples, Nov. 20, 1945.

Health and Nutrition

The standard of health in Italy is gradually improving. Health conditions were appalling during the war, owing to the scarcity of food and to the threatening spread of epidemics in the period immediately following the armistice.

In 1939 Hitler promised the peoples of the Axis a "blitz victory" and Mussolini did not then enforce food rations. In 1941, however, this was suddenly done with a vengeance, as soon as the probability of a long conflict was apparent. Only 150 Gm. of poor bread and a general daily ration that supplied each person with about 1,200 calories a day was provided. As a result all Italians began to lose weight rapidly, notwithstanding the supplements from black market sources, which were very modest, since the Nazis exploited Italy even in food. At first adults from 40 to 50 years of age began to lose weight from 12 to 25 per cent and in some cases up to 30 Kg., then young persons, children and finally the pathologically obese. The latter resisted weight loss during the years 1940 and 1941, but in 1943 not a single case of obesity was encountered from the Alps to Sicily. This indicates that insufficient food can weaken the endocrine system. They all lost weight according to a typical pattern, notwithstanding the various "types" and constitutions. The restrictions of proteins and fats caused a water imbalance, which resulted in abundant urine; this in turn led one to suspect a form of diabetes insipidus, never confirmed, however. A new restriction of carbohydrates (macaroni, bread and rice) caused those who were losing weight to become weaker and weaker. Because of the altered carbohydrate function, loss of immunity to the staphylococcic and the streptococcic infections occurred. An outbreak of abscesses and boils followed.

Malnutrition then influenced latent constitutional ailments. The most unusual forms of nonpulmonary tuberculosis appeared in adults. Thirty year old subjects were affected by meningitis, sinovitis and primary pleurisy. At the same time life in the air raid shelters, where many actually dwelt on account of the nerve racking, continuous bombardments, gave rise to mass contagion with scabies. The general thinning down took on such terrible forms that Mussolini gave orders to the editors of the chief dailies not to say a word about it, so as to avoid alarming the population. We managed, however, to get round this order, by a strange coincidence. The London *Lancet* had once published a flattering editorial on a book of mine on preventive medicine, which had been published in Bologna. Mussolini read this book. He liked it and addressed a personal letter to me declaring that the book was absolutely in keeping with his own ideas. As a result I was able to carry out a program and publish articles on preventive medicine in wartime in important political journals, exhorting the readers to get calories from nonrationed and unusual food, such as horse flesh, to add to the rations vegetables, which increased immunity because of the vitamins they contained, and to eat generously of fruit rich in mineral salts. Readers were warned against fighting weight loss by taking substances such as cod liver oil which were apt to become "diet toxic" on account of the scarcity of certain vitamin groups to counterbalance their action. In spite of the malnutrition, death by starvation was not registered in Italy as in other belligerent European countries owing to the fact that there was a natural source of vitamin B_1 in the abundant fresh vegetables.

BUENOS AIRES

(From Our Regular Correspondent)

Nov. 15, 1945.

Intrasplenic and Intracanalicular Administration of Penicillin

Dr. Mariano R. Castex and Dr. Eduardo L. Capdehourat of Buenos Aires recently reported on the intrasplenic and intracanalicular administration of penicillin. The intrasplenic route was used in a case of abscess of the spleen complicating convalescence from bilateral pulmonary abscess. The intracanalicular route was resorted to after operation in 2 cases of suppurative calculous cholecystitis. Intrasplenic injection was performed with a needle 6 or 8 cm. long, with a caliber of 0.10 or 0.12 mm. after local anesthesia of the skin. Penicillin in isotonic solution of sodium chloride, isotonic dextrose solution, the patient's whole blood, plasma, blood serum or sulfonamide solution (sulfadiazine, sodium sulfamerazine, and glucothiazole) may be used for intrasplenic injections. Any one of the solutions is well tolerated by the patient. The solution is prepared by dissolving 100,000 units of penicillin in 10 or 20 cc. of isotonic solution of sodium chloride or isotonic dextrose solution. When whole blood, plasma or blood serum is used, the penicillin is placed in 5 cc. of either isotonic solution of sodium chloride or isotonic dextrose solution, and whole blood, plasma or blood serum is added to the solution to a total quantity of 10 or 20 cc. Whole blood is withdrawn directly into the syringe which contains the penicillin solution. This precaution is necessary to prevent coagulation. The simultaneous administration of soluble sulfonamide preparations and penicillin is of value. The physical, chemical and biologic properties of the two drugs are reciprocally increased and bacterial resistance to either sulfonamide or penicillin is simultaneously controlled. The daily dose varies from 50,000 to 300,000 Oxford units. Each injection varies from 10 to 20 cc. and is given slowly. The solution is warmed by wrapping the syringe in cotton soaked in boiling water. The total dose of penicillin depends on the clinical condition. When the syringe strikes an abscess the pus or purulent material is aspirated before the injection.

Penicillin through the biliary ducts can be administered either by continuous drip or by instillation through the drainage tube after surgical opening of the gallbladder in suppurative calculous cholecystitis. The continuous drip is administered through a very fine sound which is introduced through the drainage tube, leaving a space between sound and tube for elimination of suppuration. Instillation is made directly through the drainage tube, which is closed after instillation with a clamp of the Mohr or Kocher type and kept closed for two hours after each instillation. During local administration of penicillin the patient is maintained in the Trendelenburg position, which facilitates passage of the drug deep into the liver and into the intrahepatic biliary ducts by gravitation. Penicillin passes through the common bile duct into the duodenum and the portal system and returns to the liver. Within the liver penicillin passes through the excretory canalicular system and reaches the fine lobes within the liver and the constituent cells of Remak's column through the portal system. By this procedure the hepatocystic system is in constant contact with penicillin. Bile has no influence on the effect of penicillin. A daily dose of 100,000 units is sufficient. The total dose depends on the clinical condition. Penicillin for intracanalicular use is dissolved in isotonic solution of sodium chloride, dextrose solution, plasma or blood serum. Soluble sulfonamide preparations are contraindicated because they are toxic for the liver. The quantity of solvent for the continuous drip is 100 cc. and for instillation 20 or 30 cc. Instillation is performed slowly to prevent distention of the biliary ducts. It is well tolerated, without pain and local irritation. It is indicated after operation in cases of biliary infection, suppurative angiocholitis or empyema of the gallbladder. Penicillin by the intracanalicular route is also indicated, as a routine after operation, on the excretory system of the liver with drainage in order to prevent local infection. Peptones and the products of cellular disintegration from the effect of the pyogenic course have no influence on the effect of the drug.

Studies on Old Age

A committee for studies on old age was recently appointed. Dr. Bernardo A. Houssay is the president. Drs. José González Gale, E. Eduardo Krapf, Francisco Romero and Pablo Osvaldo Wolff are members. The aim of the committee is to study the origin and general significance of the phenomena which cause old age and to extend this study to the various fields of gerontology, the organic life and inorganic nature. The somatic, mental, physical, chemical, anthropologic and philosophic aspects of the problem will be discussed. A society, to work in connection with the committee, has been organized. It will include physicians and others in the various sciences related to medicine.

Personal Items

Dr. Jose Arce, dean of the Faculty of Medicine of the University of Buenos Aires, recently resigned the position of dean of the faculty and of regular professor of thoracic surgery. Dr. Gonzalo Bosch, teacher of psychiatrics of the faculty, was appointed new dean of the faculty.

Dr. Pasteur Vallery Radot of France was the president of the French Cultural Mission in Argentina, after which he returned home. Recently the Superior Council of the National University of Buenos Aires gave him the diploma of "Doctor Honoris Causa" for his contributions to medicine.

Dr. Bruno Guenther, professor of physiopathology of the School of Medicine of the University of Conception, Chile, was recently appointed head of the Instituto de Fisiologia of the same faculty.

Marriages

George Washington Fishburn to Miss Nellie Mae Embree McIlwaine, both of Richmond, Va., in Petersburg, October 27.

Charles E. Sherwoood II, New York, to Dr. Sarah E. Prindle of New Haven, Conn., in Branford, Conn., August 20.

Walter Boudinot Rahmanop, Manchester, N. H., to Mrs. Beatrice Rowe Allen in Bedford, September 26.

Frederick Conrad Gevalt Jr., Boston, to Miss Sally Willi Young of Scarsdale, N. Y., November 10.

Robert James Ruark, Raleigh, N. C., to Mrs. Cleste Edgeton Guess in Chapel Hill, September 30.

Hiram Robertson Elliott Jr., Fairfield, Ala., to Mi Naomi Favor of Selma, September 29.

Archibald E. Senesac to Miss Louise Frances Salles, bot of New Bedford, Mass., August 25.

Mark P. Fecher, Dayton, Ohio, to Miss Lorraine Marguerit Sebek of St. Louis, September 29.

David L. Pressly, Statesville, N. C., to Miss Anita Arneso in San Antonio, Texas, October 6.

Brian T. Shorney, Detroit, to Dr. Magda E. Puppendah of St. Louis, November 3.

Rodger Browning Smith to Miss Mary Maxwell, both o Madison, Wis., recently.

Delmar O. Shields, Detroit, to Dr. Wilma R. Farrington of St. Louis, October 6.

Deaths

Isaac Donaldson Rawlings, Chicago; Northwestern University Medical School, Chicago, 1893; born in Carrollton, Ill., April 29, 1869; member of the American Medical Association; emeritus member of the Illinois State Medical Society; at one time a member of the faculty of his alma mater, where he served as assistant demonstrator in anatomy, assistant demonstrator in bacteriology and clinical medicine, instructor in clinical medicine and associate in medicine; formerly associated with the U. S. Public Health Service; joined the city health department in 1899 as a medical inspector and later appointed assistant chief medical inspector and chief of the bureau of communicable diseases; director, state department of health from 1921 to 1929; author of two volumes of "Rise and Fall of Disease in Illinois"; died in Newton, Kan., October 21, aged 76, of a fractured right femur and humerus received in a fall.

Rowland Godfrey Freeman ⊕ New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1886; professor emeritus of pediatrics at the New York University College of Medicine; member of the American Pediatric Society, New York Academy of Medicine and the Association of American Physicians; secretary from its formation in 1901 of the milk commission of the Medical Society of the County of New York until 1917 when he became chairman; consultant in pediatrics at the Sea View Hospital, Staten Island, Roosevelt Hospital, New York Foundling Hospital and the Willard Parker Hospital; author of "Elements in Pediatrics"; died November 14, aged 86, of pneumonia.

Rowland Foreman Webb ⊕ Grand Rapids, Mich.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1897; fellow of the American College of Surgeons; member of the American Association of Railroad Surgeons; member of the active senior surgical staff of the Butterworth Hospital, where he had been chief of staff three times, chief of surgery twice and where he had been intern and resident in surgery; on the courtesy staffs of the Blodgett Memorial Hospital and St. Mary's Hospital; surgeon to the Pere Marquette Railroad, New York Central Railroad and Michigan Central Railroad; died at the University Hospital, Ann Arbor, September 23, aged 70, of pneumonia.

George Eugene Dodge, San Marino, Calif.; University of Virginia Department of Medicine, Charlottesville, 1896; surgeon during Boer War on the hospital ship *Maine;* on the surgical staff of the New York Hospital in 1899; fellow of the American College of Surgeons; died September 19, aged 72, of coronary thrombosis.

Robert Hewitt Feldt ⊕ Milwaukee; Northwestern University Medical School; Chicago, 1934; assistant medical director of the Northwestern Mutual Life Insurance Company; on the staff of the Milwaukee Children's Hospital and on the associate staff of the Columbia Hospital, where he died October 8, aged 36, of rheumatic heart disease.

Amos Thomson Harrington, West Hartford, Conn.; Harvard Medical School, Boston, 1910; member of the American Medical Association; also a clergyman; physician to the Old Peoples' Home and associate physician at the Hartford Hospital, where he died October 1, aged 75, of cerebral thrombosis and hypertensive cardiovascular disease.

Arshavir Ignatius, Maywood, Ill.; University of Illinois College of Medicine, Chicago, 1916; began active duty as a captain in the medical corps, Army of the United States, on Aug. 15, 1942; assigned to Camp Gordon Johnston, Fla.; promoted to major; service terminated in 1944 because of physical disqualification; died September 12, aged 58.

Morrell Mallory Jones, Pontiac, Mich.; Detroit College of Medicine and Surgery, 1915; member of the American Medical Association; served in France during World War I; on the staffs of the Pontiac General and St. Joseph Mercy hospitals; died in the Henry Ford Hospital, Detroit, September 28, aged 54, of coronary occlusion.

Milton Emanuel Leckrone, Rochester, Ind.; Indiana University School of Medicine, Indianapolis, 1925; fellow of the American College of Surgeons; member of the American Medical Association; served an internship and as assistant superintendent of the City Hospital in Indianapolis; medical director and owner of the Woodlawn Hospital; died October 1, aged 45, of coronary embolism.

James Michael MacEvitt, Babylon, N. Y.; Long Island College Hospital, Brooklyn, 1891; member of the American Medical Association; past president of the medical board of St. Mary's Hospital and of the Holy Family Hospital, Brooklyn; died in the Southside Hospital, Bay Shore, September 3, aged 82, of generalized arteriosclerosis.

John Herbert Mudgett, Philadelphia; Dartmouth Medical School, Hanover, N. H., 1896; member of the American Medical Association; died in the Lankenau Hospital September 24, aged 73, of myocardial failure.

George Davenport Parkhurst ⊕ Fair Haven, Vt.; Bellevue Hospital Medical College, New York, 1897; for many years trustee of the Fair Haven Carnegie Library; died in the Mary McClellan Hospital, Cambridge, N. Y., September 4, aged 70, of carcinoma of the stomach.

William Courthope Poussette, Los Angeles; Trinity Medical College, Toronto, Ont., Canada, 1897; died in the Presbyterian Hospital-Olmsted Memorial September 3, aged 76, of bilateral lobar pneumonia.

Benjamin Pushkin ⊕ Baltimore; University of Maryland School of Medicine, Baltimore, 1914; assistant professor of neurology at his alma mater; specialist certified by the American Board of Psychiatry and Neurology, Inc.; on the staff of the Sinai Hospital; died September 8, aged 56, of coronary thrombosis and cardiovascular disease.

William Joseph Quigley, Chicago; Rush Medical College, Chicago, 1913; member of the American Medical Association; formerly assistant professor of medicine at the University of Illinois College of Medicine and clinical professor of medicine at the Loyola University School of Medicine; on the staffs of the Cook County Hospital and St. Anne's Hospital; died at his home in Oak Park, Ill., October 1, aged 59, of cerebral hemorrhage and coronary thrombosis.

Edward Wilson Rawls, Portsmouth, Va.; Medical College of Virginia, Richmond, 1909; member of the American Medical Association; for many years on the staff of the King's Daughters' Hospital; died September 6, aged 61, of coronary thrombosis.

John Wesley Calhoun Stephenson, St. Petersburg, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1912; fellow of the American College of Surgeons; served as a colonel on the governor's staff of Kentucky and during World War I; died in the Mound Park Hospital September 7, aged 60, of coronary occlusion.

Charles Kimball Stewart, Moorcroft, Wyo.; University of Michigan Homeopathic Medical School, Ann Arbor, 1893; served as local health officer; formerly on the staff of the Sheridan County Memorial Hospital in Sheridan; died September 12, aged 76, of cerebral hemorrhage.

Eugene Adelbert Sullivan, Amboy, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; served as health officer; president of the First National Bank; on the staff of the Amboy Public Hospital, where he died September 15, aged 68, of cerebral thrombosis and hypertension.

Frederick William Walker, Los Angeles; Rush Medical College, Chicago, 1890; died September 6, aged 86, of senility.

Frederick William Walz, Cleveland; Homeopathic Hospital College, Cleveland, 1878; served as a member of the board of education, county coroner and councilman; died in the Fairview Hospital September 20, aged 86, of arteriosclerosis.

Letitia A. Westgate, Mendota, Ill.; Northwestern University Woman's Medical School, Chicago, 1892; died September 30, aged 78, of uremia.

Bine Whitlatch ⊕ Milan, Ind.; Kentucky University Medical Department, Louisville, 1905; served as director of the State Bank and member of the school board; died September 9, aged 70, of coronary occlusion.

Margaret Barclay Wilson, Washington, D. C.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1893; formerly professor of physiology and hygiene at the Hunter College in New York; achieved a collection of about four thousand textbooks and a similar number of pamphlets in twenty different languages on foods, cookery, gastronomy and allied subjects, which she presented to the New York Academy of Medicine; died in October, aged 82, of acute congestive heart failure.

Olen L. Wise, Forest, La.; Memphis (Tenn.) Hospital Medical College, 1910; coroner of West Carroll parish; died in a sanitarium in Monroe September 7, aged 62.

Joseph Barnett Workman ⊕ Ware Shoals, S. C.; Medical College of the State of South Carolina, Charleston, 1907; died in the Greenwood (S. C.) Hospital September 20, aged 67, of injuries received in an automobile accident.

DIED WHILE IN MILITARY SERVICE

George Hudson Ebbett, Houlton, Maine; McGill University Faculty of Medicine, Montreal, Que., Canada, 1936; born in Hodgdon, Maine, July 21, 1909; member of the American Medical Association; interned at the Monmouth Memorial Hospital in Long Branch, N. J.; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on Dec. 2, 1939; began active duty in the medical corps, Army of the United States, on Feb. 10, 1941; the first assignment was at Fort Benning, Ga., which was followed by duties in various training centers in the United States; promoted to captain on June 1, 1942; in August 1943 went overseas and was recalled to the United States in 1944, when he was assigned to the orthopedic service in the hospital at Westover Field, Mass., where he died July 27, aged 36, of second degree burns received when his home caught fire.

Donald Renwick Ferguson, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1916; born in Swarthmore, Pa., Nov. 21, 1889; member of the American Medical Association; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; professor of clinical medicine at his alma mater; served as president of the Philadelphia County Homeopathic Medical Society; on the staffs of the Children's Hospital and St. Luke's Hospital; consulting cardiologist at the Women's Homeopathic Hospital; visiting physician at the Hahnemann Hospital; served overseas during World War I; began active duty as a major in the medical corps, Army of the United States, on Sept. 25, 1942; died in Station Hospital, Camp Shanks, N. Y., August 27, aged 55, of cerebral hemorrhage.

Walter Robinson Finton, Jackson, Mich.; University of Michigan Medical School, Ann Arbor, 1936; born in Jackson, Mich., July 9, 1911; member of the American Medical Association; interned at the Hurley Hospital in Flint; began active duty as a first lieutenant in the medical corps, Army of the United States, on Sept. 22, 1942; trained at Miami, Fla.; stationed at the Army Air Base at Walla Walla, Wash., for four months; on June 1, 1943, assigned to the Second Air Force and sailed for European duty; served in England, Ireland, France and Germany; promoted to captain; died in the Sixty-Eighth General Hospital in France July 15, aged 34, of acute infectious hepatitis.

Glenn Ellwood Harrison, Mason City, Iowa; State University of Iowa College of Medicine, Iowa City, 1928; born in Prescott, Iowa, Feb. 24, 1903; member of the American Medical Association and the American Academy of Pediatrics; on the staff of the Park Hospital; interned at the University Hospitals in Iowa City, where he served a residency; served a residency at the Duke Hospital in Durham, N. C.; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on Jan. 6, 1930; began active duty on Dec. 12, 1940 as a captain, assigned as chief of the contagious disease service, Base Hospital, Camp Joseph T. Robinson, Ark.; became the surgeon of the eighth port of embarkation at Boston; commander of the Thirty-Fifth Hospital unit at Corsica, which was awarded the meritorious service unit plaque; promoted to major, lieutenant colonel and colonel; died August 31, aged 42, of coronary heart disease.

Lewis McCurdy Jones, Opelika, Ala.; Emory University School of Medicine, Atlanta, 1937; interned at the Hillman Hospital in Birmingham, where he served a residency in obstetrics and gynecology; began active duty as a first lieutenant in the medical corps, Army of the United States, on Dec. 15, 1940; promoted to captain on Oct. 29, 1941; served overseas with a general hospital in England, 1943-1944; killed June 17, aged 32, in an automobile accident near Camp Rucker, Ala.

Martin Joseph Keane ⊕ Riverdale, Md.; Georgetown University School of Medicine, Washington, D. C., 1930; interned at the Georgetown University Hospital in Washington, D. C.; formerly instructor in bacteriology and in clinical surgery at his alma mater; commissioned a captain in the medical corps, Army of the United States, on Nov. 20, 1944; died in the Walter Reed General Hospital, Washington, D. C., September 20, aged 40, of congestive heart failure.

Howard Dillon Maxwell ⊕ Alliance, Ohio; Ohio State University College of Medicine, Columbus, 1930; interned at the Youngstown Hospital in Youngstown; began active duty as a captain in the medical corps, Army of the United States, on September 1942; promoted to major, Nov. 7, 1944; served overseas in New Guinea and in the Philippines; died at the Fletcher General Hospital in Cambridge, Ohio, August 12, aged 42, of pneumonia.

Arch Lavere Oldaker, Lakewood, Ohio; Western Reserve University School of Medicine, Cleveland, 1929; member of the American Medical Association; interned at St. Vincent's Charity Hospital in Cleveland; formerly resident physician at the Lakewood City Hospital; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on June 13, 1929; promoted to captain, June 23, 1939; began active duty in 1941; died in the Philippine Islands May 8, 1942, aged 41, of malaria.

John Josiah Redfield, North Platte, Neb.; University of Nebraska College of Medicine, Omaha, 1942; interned at the Eastern Maine General Hospital in Bangor, Maine; began active duty as a first lieutenant in the medical corps, Army of the United States, on Aug. 10, 1943; died in Columbus, Ga., August 22, aged 28, of coronary sclerosis.

Robert Lewis Screen, Martinsville, Va.; Meharry Medical College, Nashville, Tenn., 1942; interned at the City Hospital in Winston-Salem, N. C.; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 7, 1944; sailed for overseas duty with the 92d division in October 1944; killed in Italy April 8, aged 27.

James McGeough Sullivan, San Francisco; St. Louis University School of Medicine, 1923; diplomate of the National Board of Medical Examiners; member of the American Medical Association; lieutenant colonel, medical corps, Army of the United States; died in Honshu Island, Camp Fukuoka, Japan, Jan. 31, 1945, aged 52, of acute colitis.

Walter Low Tatum, Salisbury, N. C.; Jefferson Medical College of Philadelphia, 1922; born in Salisbury, N. C., June 5, 1899; interned in St. Joseph's Hospital in Philadelphia; past president of the Rowan-Davie Counties Medical Society; served as county coroner for many years; formerly chief of staff of the Rowan Memorial Hospital; served as president of the Fourth Corps Area council of the National Reserve Officers Association of the United States; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on April 28, 1925; became a captain on July 8, 1929, a major on Aug. 1, 1934 and a lieutenant colonel on Oct. 17, 1940; began active duty on Feb. 28, 1941; died in Frankfort, Germany, August 1, aged 46, of arteriosclerotic arterial hypertension.

Wiley Kellett Thorne, Mountain Grove, Mo.; Washington University School of Medicine, St. Louis, 1943; interned at the St. Louis City Hospital; commissioned a first lieutenant Dec. 12, 1943 in the medical corps, Army of the United States; died in Saipan June 20, aged 26, when a carbine was accidentally discharged.

Thomas Edgar Wyatt Jr., Marshfield, Wis.; Vanderbilt University School of Medicine, Nashville, Tenn., 1935; born in Elkton, Ky., on May 21, 1910; member of the American Medical Association; interned at the New York Hospital in New York; served a residency in surgery at the Vanderbilt University Hospital in Nashville, Tenn.; an associate surgeon with the Marshfield Clinic; fellow of the American College of Surgeons; commissioned a first lieutenant in the medical reserve corps of the U. S. Army in 1935 and began active duty as a captain on Oct. 25, 1940; promoted to major; left for overseas service early in January 1942; while on foreign service attended the British army specialist schools of neurosurgery in Oxford, maxillofacial surgery in East Grinstead and chest surgery in London; an operating surgeon with the first task force to land in northern Ireland in 1942 and later with advance medical units in Normandy, France, Belgium, the Netherlands and Germany, with the First and Ninth armies, 41st Evacuation Hospital; among the decorations awarded him were the Bronze Star and citations from the king of England and the President of the United states; died on train near Valley Forge, Pa., August 12, aged 35, of edema of lungs with dilatation of the heart.

Correspondence

RESTLESS LEGS

To the Editor:—The editorial "Restless Legs" in the issue of November 24 was of great interest because I too have had this condition. My observations, both of myself and of my patients, convince me that this symptom is associated with either chronic nonspecific prostatitis or testosterone deficiency or a combination of the two. This symptom is probably more common than one might suspect, but for some unknown reason patients with prostatitis seldom volunteer the information that they have this complaint. About half of my prostatitis patients will admit having "restless legs" if carefully questioned, and treatment directed solely at the prostate gives relief.

A general practitioner seldom sees enough of one type of patient to be able to draw any accurate conclusions. However, this observation may be of interest to those who can study a sufficient number of these cases and can make statistical studies from which valid conclusions can be drawn.

J. A. WINTER, M.D., St. Joseph, Mich.

To the Editor:—Meralgia paresthetica, Roth's or Bernhardt's disease, was described many years ago (Goldstein, Hyman I.: *Am. J. M. Sc.* **162**:720 [Nov.] 1921). While typically this syndrome affects the thighs laterally and anteriorly, it appears to resemble in some respects the paresthesias of "restless legs" (Wittmaack-Ekbom syndrome). The editorial in THE JOURNAL, November 24, discusses crurum paraesthetica and the painful crawling cold sensations, but no mention is made of this similarity to Roth's or Bernhardt's disease, and perhaps mention should be made of Solomon Solis-Cohen's "vasomotor ataxia" (*Am. J. M. Sc.* **107**:135, 1894), Osler's "crural paresthetica" (Osler, William: On Certain Unusual Forms of Paresthetica Meralgia, *J. Nerv. & Ment. Dis.* **24**:131, 137, 1897), Erb-Hunt-Kirstein's dysbasia angiosclerotica and Moebius's akinesia algera. Perhaps Ekbom (*Acta med. Scandinav.*, supplement 158, 1945) has only revived previously described syndromes by Wittmaack (1861), Roth (1895) and Bernhardt (1895), as so frequently happens in medical literature.

HYMAN I. GOLDSTEIN, M.D., Camden, N. J.

SUBACUTE BACTERIAL ENDOCARDITIS

To the Editor:—The article "Penicillin in Subacute Bacterial Endocarditis" (THE JOURNAL, November 24, p. 841) by Flippin et al. interested me very much, especially their advice to eradicate secondary foci of infection. They enumerated the tonsils, teeth and middle ear as probably the most frequent sites of focal diseases. To these sites I still firmly believe the spleen should be added as the most likely source of reinfection and the site from which the greatest amount of bacterial toxins is absorbed (Reisman, David; Kolmer, J. A., and Polowe, David: Splenectomy in the Treatment of Subacute Bacterial Endocarditis, *Am. J. M. Sc.* **192**:475 [Oct.] 1936. Polowe, David: Splenectomy in the Treatment of Proved Subacute Bacterial Endocarditis, *Arch. Surg.* **38**:139 [Jan.] 1939).

It is truly stirring to live in an age that is witnessing the conquering of subacute bacterial endocarditis. The controlled use of heparin will probably add to the percentage of cures effected by penicillin. And the judicious eradication of secondary foci of infection such as the tonsils, teeth, middle ear and spleen may bring the total of permanent cures closer to the 100 per cent mark, where we'd like to see it. The person who was the subject of my report in 1939 is still alive and well.

DAVID POLOWE, M.D., Paterson, N. J.

RECURRENT HEADACHE RESULTANT FROM MALARIA

To the Editor:—I was interested in reading the case report of recurrent headache resultant from malaria appearing in the October 27 issue of THE JOURNAL.

Dr. Kaplan's experience with headache during the course of chronic malaria is, as he states, not altogether unusual. It is my observation, however, that the headaches seldom attain the severity he reports for his case, and they are not present or prominent in the vast majority of cases.

In his comment Dr. Kaplan states that "malaria in the Pacific area is a common disease and will become much more common in the United States as more of our fighting men return from zones where they were exposed to the Anopheles maculipennis mosquito." I find it difficult to agree with much of this sentence. Malaria is certainly common on the malarious islands of the Pacific, but the vast Central Pacific, including Guam, Saipan, Iwo Jima, Samoa, Hawaii and many other important bases is malaria free. Anopheles maculipennis mosquitoes do not occur in the Pacific or in eastern Asia, the common Pacific vectors during this war being Anopheles farauti, Anopheles punctulatus and possibly Anopheles minimus, Anopheles hyrcanus, Anopheles sinensis and Anopheles sundaicus in the Philippine Islands and in Asia.

Malaria in the armed forces has declined to extremely low levels as compared with the incidence in 1943 and early 1944 and is at present comparatively rare in naval hospitials. Vast numbers of men with malaria have returned to the United States since early in 1943 without any significant outbreaks or increase of the disease during this time. The majority of men now being returned either have not had malaria or have late and relatively quiescent cases. It must be appreciated that the bulk of troop malaria was acquired early in the war before effective malaria control was established. These early cases have had two or three years to subside, and our statistics clearly show that such subsidence has occurred. In that the last three years have failed to produce the often predicted rise in malaria as a result of exotic infection, it is sincerely doubted that it will occur now or in the immediate future.

Dr. Kaplan goes on to say that in a number of cases with recurrent headaches but without parasitemia he was able to demonstrate parasites invariably by blood film examination after administration of 1 Gm. of quinine sulfate or 0.12 cc. of epinephrine. The use of quinine as a provocative measure has not to my knowledge ever been reported before and requires confirmation. The general experience is that administration of quinine will cause such parasites as are in the circulation to disappear immediately. There was a general rule in many overseas hospitals during this war that in cases of uncomplicated malaria antimalarial drugs would not be administered until after a laboratory diagnosis of malaria was established. Epinephrine as a provocative agent is of dubious value. While it has had its adherents during the present war, several very capable hospital groups had no success whatever with it, and the statement that it invariably induces a demonstrable parasitemia would be difficult to support in any circumstance. The possibility, of course, exists that Dr. Kaplan assumed that other men with headaches who did not respond to his provocative measures did not have malaria.

FRED A. BUTLER, Commander (MC), U.S.N.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Abortion Induced by Sanipractor.—Mrs. Dennis consulted one of the defendants, a woman sanipractor, Feb. 13, 1940, relative to a backache. Apparently the sanipractor administered no treatments on that visit, merely suggesting to her patient that the discomfort might be caused by a cyst, tumor or tipped uterus. However, the sanipractor instituted a course of biweekly treatments February 20, which continued through March 22 and which consisted of "adjustments" to her back, electrotherapy administered by a device which used pads placed on her back and abdomen, and treatments with a vibrating device having a belt against which the patient leaned, turning herself so that contact was made around the abdomen and back. The patient frequently suggested to the sanipractor that she might be pregnant, but the sanipractor assured her she was not although the practitioner made no tests, such as the Friedman or Aschheim-Zondek test, which concededly is from 94 to 98 per cent accurate. Apparently about March 31, to allay the patient's suspicions as to pregnancy, the sanipractor examined her internally and, according to her testimony,

> She took an instrument, a long instrument, and poked up into the uterus and it was very painful, it was awfully painful. And she said—well, she said, "If you was pregnant the mouth of the uterus wouldn't be open." And she drew blood. I saw blood on the end of that instrument.

Seemingly the patient then began to hemorrhage and the sanipractor packed her vagina, telling her that "it would hold the uterus in place, that that was what was causing the pain." The patient continued to hemorrhage and apparently on April 6 visited the sanipractor, who told her "the uterus was tipped badly and it was polyps that was passing and that was good" and that when those would pass away "it would be just fine." She then packed the vagina again "to hold the uterus in position, it would take the pressure, relieve that pain." Against the sanipractor's advice, the patient started on an automobile trip but after going a few miles the pain became so unbearable that she returned to town and was attended by the sanipractor's husband, apparently another sanipractor, who had her hospitalized immediately, where she was attended by a physician. The physician found her in the process of aborting and performed a curettement. Six weeks later he removed both fallopian tubes and a cyst from the right ovary. Subsequently the patient and her husband sued the sanipractor and her husband for malpractice. From a judgment in favor of plaintiffs for $5,000, the defendants appealed to the Supreme Court of Washington.

The defendants in general questioned the sufficiency of the evidence to sustain the verdict on which the judgment was based. They claimed that the testimony of the patient respecting the invasion of the uterus was inadmissible because she could not have testimonial knowledge. We will assume, said the court, without deciding, that this testimony was essential to the patient's case and that without it the evidence would be insufficient to sustain the verdict. This is for the reason that the other treatments, stoutly maintained as not being contraindicated in cases of pregnancy, might have left the case in the realm of speculation. However, as to this evidence of invasion of the uterus, the sanipractor stands on a denial rather than on the proposition that an abortion following an invasion of the uterus would be speculative as to its cause. The invasion of the uterus is based solely on the testimony of the patient as previously set out. We quote the sanipractor's first contention:

> Picture the patient lying flat on her back on a table and the doctor working over her. Could the patient see where the instrument was "poked"? It would be a human impossibility for her to so do unless she was a contortionist. How did she know then, by the sense of feeling? I think not, for it is common knowledge that there are other cavities and orifices entering into the vaginal canal, such as the urethra, and I do not believe the sense of touch is developed to such an acuteness that the layman could know whether an instrument was inserted up into the uterus or some other opening or cavity within the vaginal canal.

No objection was made to the admission of the testimony as quoted earlier in this opinion, but in any event we would not be prepared to say that the patient lacked testimonial knowledge as to the things testified to.

The sanipractor further contended that the testimony of the patient "as to where the instrument was poked" invades the realm of the expert and is beyond the knowledge of ordinary laymen and was therefore inadmissible. However, said the court, no objection was made to the testimony when it was introduced. In any event, we are not prepared to say that it falls in the realm of things beyond common experience of women in general, or requires such knowledge, skill or training not possessed by women generally. Lastly, the appellants contended that the trial court in examining the sanipractor commented on the evidence and that this was reversible error. As an example, the following questions by the court and answers by the sanipractor on the witness stand were relied on:

"The Court: What do you mean? This treatment was not what?

"The Witness: There is none of it that is contraindicated in pregnancy, none that we wouldn't use in a pregnancy case.

"The Court: Did you use the electrical vibrating belt machine? A. I never use that on a pregnant woman. It wouldn't tend to reason—

"The Court (interrupting): Well, I asked you if you used it in this case?

"The Witness: No. It would be entirely foolish for me to first go to work and pack her and work to stop the flow and then put on an electric vibrator to start a flow. I would be working against myself.

"The Court: Well, did you diagnose her case as pregnancy?

"The Witness: I didn't diagnose her case. It yet had not been diagnosed when she quit. She was feeling so much better. She had just been in the office thirty days from the day she started treatment.

"The Court: You had not yet diagnosed her?

"The Witness: No, I had checked her on the machine and followed up to see whether there was any albumin. She had two checks on that."

In any event, said the Supreme Court, the appellants cannot raise this question when there was no objection made in the trial court. However, the court could see no impropriety in the trial court's conduct. It is beyond controversy, said the court, that a trial court has wide discretionary powers in the trial of a cause and is not prohibited from questioning a witness. Such a course, it is true, may constitute a comment on the evidence where it is improperly done. To constitute a comment on the evidence, however, it must appear that the attitude of the court toward the merits of the cause must be reasonably inferable from the nature or manner of the questions asked and things said. This record, in our opinion, does not disclose any grounds for the jury to infer that the court had or expressed an opinion.

The judgment against the sanipractors was affirmed.—*Dennis v. McArthur, 158 P. (2d) 644 (Wash., 1945).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Coccidioidomycosis.—The observation of a number of cases of coccidioidomycosis in soldiers engaged in a construction project near Banning, Calif., suggested to Willett and Weiss the existence of a new endemic region. They made repeated skin tests on 573 soldiers (Negro and white) performing a dusty type of work at the edge of the desert. One hundred and thirty-five "change overs" from negative to positive skin reactions were found, of which 83 were hospitalized with acute pulmonary coccidioidomycosis. The 135 cases which showed a change in the skin reaction from negative to positive constitute the epidemiologic group by which the area of endemicity was established. The region in question is a triangular one bounded by Banning and Needles, Calif., and Yuma, Ariz. In the eight months subsequent to the epidemiologic survey 17 additional patients with acute pulmonary coccidioidomycosis have been hospitalized from the desert area, thus making a total of 100 hospitalized cases, almost equally divided between Negro (49) and white patients (51). The disease appeared to be more severe in Negroes. Cavities in 2 white soldiers either closed or showed a tendency to close at the last examination. Of 4 cases of cavitation in Negroes, only 1 closed. The disseminated form, which is by far the most serious type, occurred in 4 patients, all of whom were colored and 1 of whom died. This patient had a generalized miliary dissemination involving virtually every organ and system of the body except the gastrointestinal tract and central nervous system. Of the other 3 patients, 2 had dissemination to bone and the last dissemination to muscle. The average case of acute pulmonary coccidioidomycosis has a good prognosis for complete recovery. There is no "specific" for the disease. Measures such as acetylsalicylic acid, codeine in small doses or other mild analgesics are usually quite sufficient for the acute symptoms. Vaccines have been used with questionable results. Surgical excision has been effective in local abscesses caused by the fungus.

Sickle Cell Disease.—Murphy and Shapiro studied a patient with sickle cell disease for twelve months. He was a Negro aged 21 who complained of generalized muscle and joint pains. He had had frequent and severe attacks of what were believed to have been episodes of acute rheumatic fever since the age of 3 years. The first blood count established the diagnosis of sickle cell disease. During the first ten days the clinical picture continued unchanged, with a low grade fever and migratory pains. Thereafter the patient's course was characterized by the so-called active and latent phases alternately of sickle cell disease. Altogether there were seven "active" periods. Five of these occurred in the form of dramatic crises. The remaining two assumed a less striking pattern. Accompanying the crises were fever and disseminated pains produced by multiple infarctions, which may have been visceral as well as skeletal. Hemolytic aspects representing resolution of thrombi and disintegration of the sickled cells are prominent. The diffuse infarcts stem from the abnormal shape and other physical characteristics of the sickled erythrocyte. During the time a susceptible cell retains the normal shape it is indistinguishable from normal erythrocytes. The act of sickling, however, renders it elongated and rigid, making capillary passage difficult. As the sickled forms gain prominence in the blood stream they eventually form a mechanical impaction, delaying the capillary flow, and thrombosis takes place. This constitutes the fundamental pathologic lesion of sickle cell disease. All erythrocytes of a subject with the asymptomatic sickle cell trait are capable of assuming the abnormal form and differ from those of persons who exhibit the crises only in that they possess a higher threshold of sickling. Susceptible red cells exhibit increased tendency to sickling as they mature. The abnormal form tends to increase progressively during the quiescent periods until mechanical obstruction and thrombosis of capillaries occur. With each thrombosis there are liberated into the circulation certain coagulating bodies (thrombin, thromboplastin) which further enhance thrombosis and accelerate the precipitation of sickled red cells. A self-perpetuating sickle cell "crisis" is thereby inaugurated, which gains momentum until the major part of the sickled cells are destroyed and the blood is again "rejuvenated" by release into the circulation of immature normally shaped cells. Anticoagulant therapy appears to be inadequate to prevent a crisis. If at the abrupt onset of a crisis anticoagulants might postpone the thrombotic tendency, they could not prevent the increased tendency of the cells to sickle as they grow older, which tendency leads inevitably to the vascular occlusions.

Chemotherapy and Allergy Management in Bronchiectasis.—Thomas and his associates found that of 190 consecutive cases of bronchiectasis approximately one half had allergy of the respiratory tract. A clinical study was made of 75 selected cases of bronchiectasis to evaluate sulfonamide therapy and allergy management in treatment. In 55 of these cases an allergy of the respiratory tract was an etiologic or complicating factor. Twenty-three patients received sulfonamide drugs as the chief or only therapeutic measure and were observed for four months to four years. Twenty-two of these patients showed definite improvement with reduction of cough and expectoration. Twenty-one cases treated chiefly or wholly with allergy management were observed for from one to four and one-half years. Fifteen of this group showed frank improvement with reduction in cough and expectoration. In 31 cases combined allergy and sulfonamide therapy was used. Twenty-six cases were found to show at least 25 to 100 per cent improvement in cough and expectoration. They were observed for six months to five years. Exacerbations were frequent in all groups, but almost invariably if sulfonamide drugs were repeated when symptoms first began to return to their former severity continued improvement could be maintained. Likewise, exacerbations occurred often when the allergy program was discontinued.

Possibility of Soldiers with Pacific Plasmodium Vivax Infecting Anopheles Quadrimaculatus.—The studies here reported by Watson were carried out at the Kennedy General Hospital. Anopheles quadrimaculatus mosquitoes were fed on soldiers with relapsing Plasmodium vivax infections presumably acquired in Pacific war areas. Feeding of mosquitoes was done without reference to gametocyte levels, number of relapses experienced, origin of strains or any other variable. Some patients had received two 0.6 Gm. doses of quinine or totaquine before the mosquitoes were fed. After incubation for fifteen days in an air conditioned room these mosquitoes were examined for salivary gland infections. An overall infection rate of 11.8 per cent was found for 1,426 mosquitoes which had been fed on a total of 117 cases, representing 87 different patients. The highest infection rate (17.7 per cent) was obtained in lots of mosquitoes fed on patients with asymptomatic parasitemia. The infection rates for mosquitoes fed on patients who had received treatment were not significantly different from those fed on patients who had received no treatment. It is concluded that many, if not all, strains of P. vivax from Pacific war areas can be transmitted by A. quadrimaculatus and that returning soldiers with such infections may be responsible for the establishment in this country of epidemic or endemic foci of imported vivax strains.

Diagnosis of Malaria by Fluorescence Microscopy.—Metcalf reports a method for fluorescent microscopic identification of the plasmodia of human malaria in blood films. Of fourteen fluorochromes studied, berberine sulfate and rivanol gave the best visualization of plasmodia with the fluorescent microscope. Because of its simplicity the method might be of value in routine malaria surveys. The employment of fluorescent dyes as histologic stains, which are then irradiated with ultraviolet rays, produces a light source in the microscopic object itself. This results in perfect conditions for image formation in microscopy in that refractive difficulties inherent in condensing lenses are eliminated. This fact, coupled with the dark field, produced results of extreme sharpness and clarity. The parasites appear as luminous bodies within the dark outlines of erythrocytes; they can be readily observed even in rapid scanning of the slide.

Kaposi's Varicelliform Eruption.—Blattner and his co-workers at the St. Louis Children's Hospital treated a patient who had Kaposi's varicelliform eruption. A virus etiology had been suggested, but no etiologic agent had been identified. The authors made an attempt to isolate the infectious agent from the cutaneous lesions of their patient, a boy aged 15 months who had an atopic eczema since the age of 6 weeks and an acute exanthem associated with high fever for five days. Fluid removed from cutaneous vesicles on the fifth and sixth days of illness was cultured by bacteriologic methods, pure cultures of Streptococcus hemolyticus and Staphylococcus aureus resulting. Material from these vesicles was inoculated on the scarified cornea of a rabbit. Lesions were noted within three days. On the fourth day the rabbit cornea was removed, washed in sterile saline solution and triturated in tryptose-phosphate broth in an agate mortar. After centrifugation, the supernatant fluid was Seitz filtered and inoculated into mice intracerebrally and onto the retracted chorioallantois of embryonated hen's eggs. The mice developed convulsions and died in from two to four days, and by the fourth day numerous small, pocklike lesions were observed on the chorioallantoic membranes. Other samples of vesicular fluid inoculated directly onto the chorioallantoic membrane produced lesions in from four to five days. The fact that the virus was isolated not only by means of the rabbit's cornea but also directly on the chorioallantois would seem to exclude a latent herpes virus which might have been reactivated in the rabbit by experimental manipulation. The virus was identified as a member of the herpes group. The authors conclude that a strain of herpes virus is the etiologic agent involved in at least some of the cases diagnosed as Kaposi's varicelliform eruption. Strains of herpes were isolated and identified in two other laboratories.

Hemolytic Disease of the Newborn.—Leonard reviewed records of 55 infants with hemolytic disease who were treated in the pediatric service between July 1938 and June 1944. The infants showed most or all of the characteristic clinical signs: jaundice, progressive anemia, hepatomegaly, splenomegaly, hemorrhage, edema, excessive numbers of nucleated red blood cells in the circulating blood and the typical pattern of Rh negative blood in the mother and Rh positive blood in the father and baby. Only liveborn babies were included. The clinical picture in these 55 cases varied greatly. A high incidence (44 per cent) of nonspecific diarrhea was noted. The effects of transfusion with Rh positive, Rh negative blood and bank blood not typed for the Rh factor were compared. Immediate results following transfusion in raising hemoglobin and improving clinical condition were good, but Rh negative blood transfusions caused a better sustained rise in hemoglobin, fewer reactions and lower mortality. Nineteen infants died. One of the chief causes of death was hemorrhage. Jaundice out of proportion to or in the absence of anemia was attributed to impaired liver function. This thesis was supported by low prothrombin levels responding poorly to vitamin K administration, fatty degeneration and necrosis of the liver. Plasma infusions were preferred in this type of patient. The prominence of hemorrhagic tendencies in patients with hemolytic disease of the newborn was emphasized and its relation to low prothrombin levels demonstrated. Administration of vitamin K to donors of Rh negative blood was suggested as a means of raising the prothrombin levels of affected infants.

Urea and Sulfonamides in Treatment of Gonorrhea. J. G. Menville and C. W. Ross.—p. 211.

Transurethral Prostatic Resection in Advanced Renal Insufficiency.—Greene and Thompson review observations on 54 patients who entered the hospital with renal insufficiency due chiefly to prostatic obstruction and on whom transurethral prostatic resection was performed in the presence of severe renal insufficiency In every case the prostatic resection was performed at a time when the blood urea, though reduced, still remained 100 mg per hundred cubic centimeters or more, the value of 100 mg per hundred cubic centimeters to denote renal insufficiency was selected because this represents severe impairment of renal function The authors conclude that transurethral prostatic resection can be performed safely on patients suffering from advanced renal insufficiency and these patients are no longer obliged to lead a "catheter life" The important features of management are (1) improvement or restoration of the acid base metabolism by the intravenous administration of suitable fluids and the treatment of anemia by blood transfusions, (2) maintenance of a urinary output of 2,000 to 3,000 cc daily, thereby producing a fall in the nitrogenous waste products present in the blood, (3) drainage by urethral catheter for as short a period as possible, suprapubic cystotomy with its attendant mortality not being necessary, (4) operation at the first indication that the value for the blood urea is no longer falling but has become stabilized and (5) completion of the resection within forty-five minutes The period of preoperative and postoperative hospitalization for patients with advanced renal insufficiency is comparatively short when they are treated by transurethral prostatic resection Longevity following prostatic resection among patients of this group warrants the procedure Gastrointestinal symptoms due to renal insufficiency have been relieved in spite of the fact that renal function remains impaired

Stones in Urinary Tract in Wet Tropics—According to Davalos it has long been known that urinary stones are much more prevalent in some countries and districts than in others, and this unequal distribution has given rise to numerous theories as to the influence of climate, soil and the dietary habits of a people on the formation of stones The geographic distribution of lithiasis in South America has received much less study than it has in other parts of the world, but available statistics indicate that urinary stones are common throughout the southern part of the continent, especially in the northern and central districts of Chile and in many sections of Argentina In Brazil cases of urinary stone are common in the northeastern portion and numerous in the southern section but are rare in the Amazon Valley The latter region has the same climate as the Ecuador Mountains—that is, hot and humid the year round—and the living conditions and diet of the inhabitants are essentially similar Panama is another locality with approximately the same climatic conditions and dietary habits, and here also lithiasis is infrequent In investigating the reasons for the almost complete absence of urinary stones in the tropical regions of Ecuador, Davalos approached the subject from three angles (1) the local geographic conditions, (2) the diet of the people and (3) urine examination Among 60,000 patients observed in the southern part of Ecuador there was not a single one with urinary lithiasis The author stresses that in the wet tropics the high temperature induces profuse perspiration, which, by eliminating a considerable part of the metabolic output through the skin, materially decreases the eliminatory strain on the kidneys The low urinary p_H prevents the growth of urea splitting organisms (proteus, ammoniac, coli), and there is no precipitation of phosphates and carbonates in the urinary tract It would appear that, in tropical Ecuador at least, climatic conditions are primarily responsible for the rarity of urinary lithiasis, since the poorly balanced vitamin deficient diet of the inhabitants, far from preventing stone formation, is conducive to it

Immersion Foot Syndrome—Ungley and his associates consider immersion foot as a disorder characterized by chilling of the tissues distinct from freezing or frost bite The condition is most frequently seen in shipwreck survivors but may result from any circumstances in which there is prolonged exposure of the extremities to moist cold Trench foot presents a clinical picture similar to that of immersion foot, and the two conditions are akin if not identical The immersion foot syndrome has four phases During the period of exposure the limbs are numb In the second or prehyperemic phase the sensory disturbances which occurred during exposure continue For some hours after rescue survivors are frequently unable to maintain their balance or, if able to walk, they describe the sensation as "walking on air" or 'walking on cotton wool' There is a "stocking" type of sensory disturbance During the third or hyperemic stage the previously cold, pulseless feet become hot and flushed The onset of the hyperemic stage may be accelerated by warming the feet, a procedure the authors condemn With hyperemia there is continuous diffuse pain Patients are restless and require large doses of sedatives and analgesics About the seventh to tenth day after rescue, pains of a shooting or stabbing character not unlike the lightning pains of tabes dorsalis occur radiating from the center of the foot to the tips of the toes These pains are aggravated by heat and relieved by cold, they are most severe when the feet are dependent, after exercise and when the feet are warming, e g after getting into bed at night Exceptionally, attacks of stabbing pain may be precipitated by micturition, defecation, coughing or yawning. In the early hyperemic stage movements of the ankle and toes are hampered by swelling. As edema subsides, weakness and wasting of the intrinsic muscles of the foot become apparent and the toes become clawed. When patients begin to walk they have a flat-footed springless gait. The fourth or posthyperemic stage may be absent; mild cases pass from the phase of hyperemia to normal. In the moderately severe cases the first indication that a change is about to occur is that the feet, previously consistently warm, are cool. Later still the feet become permanently cold and are "cold sensitive." In some cases the feet are also heat sensitive; after exercise or when the patient is in bed the feet become unbearably hot and he is forced to take measures to cool them. Hyperhidrosis frequently accompanies the cold sensitivity. Cold therapy is of value for the relief of pain in the hyperemic stage but should not be used in the prehyperemic stage. Sympathectomy and other measures designed to increase the peripheral circulation should not be employed immediately but may have a place in the treatment of the later cold sensitive state.

*Periarteritis Nodosa or Kussmaul-Maier Disease: First Case Diagnosed in Infant During Life; Rapid Recovery from Therapy with Sulfapyridine and Acetylcholine. J. Legros.—p. 112.

Periarteritis Nodosa in an Infant.—Legros reports the occurrence of periarteritis nodosa in a girl aged 9 months. There was edema of the lower extremities, a macular rash with numerous purpuric spots and palpable small subcutaneous nodules. The muscles of the lower and of the upper extremities were extremely tender. Necrosis of the purpuric areas occurred within twenty-four hours. Diagnosis of periarteritis nodosa was made. Biopsy of a nodule revealed a circumscribed necrosis of the epidermis with clear demarcation of the living portion of the skin. The necrotic portion of the skin was characterized by perivascular infiltration with alteration of all the layers of the corium. The nodule appeared as a cone with the base composed of necrotic epidermis and at the summit an artery with the lumen obstructed by a fibrinous thrombus, poor in cells. The intima appeared partly disorganized. The two accompanying veins were not involved. The bacteriologic examination was negative except for a hemolytic streptococcus, which was cultured from the pharynx. A positive reaction was produced in the patient and in her mother by a subcutaneous injection of a heated culture of this streptococcus, while a negative reaction was observed in 4 other infants. Treatment consisted of one-fourth tablet of sulfapyridine given eight times daily and of 0.1 Gm. of acetylcholine administered twice daily by the intramuscular route. This therapy was continued for five days. Within two days the temperature dropped from 104 F. to normal and the edema was considerably reduced. The edema and muscle pain subsided completely within the next three days. The necrotic crusts separated, leaving scars which resembled those seen occasionally following chickenpox. The rapid healing of the cutaneous lesions was striking. This supports the concept of an allergic origin of the disease, which was suggested also by the positive cutaneous reaction of the patient and by the negative reaction of other infants. The concept of sepsis due to the streptococcus is suggested by the effectiveness of chemotherapy. Sulfonamide therapy appears to be indicated in the acute stage of this disease. Two cases of periarteritis nodosa in infants have previously been published but were diagnosed only on postmortem examination. The author's case is the first diagnosed during life.

Grave Malnutritions at Present Time: Bioclinical Remarks on Athrepsia. G. Mouriquand.—p. 441.
*Treatment of Nitrogen Deficiency of Various Origins by Means of Protein Hydrolysates. L. Chevillard, R. Jacquot and J. Roche.—p. 442.
Significance of Presence of Tubercle Bacilli in Sputum of Patients with Pulmonary Tuberculosis Treated in Sanatorium. J. C. Levaditi.—p. 443.

Protein Hydrolysates in Nitrogen Deficiencies.—Chevillard and his associates point out that it is possible to supply the nitrogen needs of man by the administration of sufficient amounts of a mixture of amino acids. Since, for economic reasons, it is not feasible to do this with pure amino acids, investigators have resorted to protein hydrolysates. Those which must be derived from complete proteins (casein or meat) are of two types. One type, the hydrolysates resulting from enzymatic digestion, can be employed without any addition, for their amino acids have not been altered by proteolysis and they contain amino acids and polypeptides of low molecular weight. Other types are products of a total acid hydrolysis of proteins with added tryptophan. The nutritive value of these diverse products is the same, but they are administered differently. The preparations of enzymatic origin are administered by mouth in a 5 per cent solution which also contains from 7.5 to 10 per cent of dextrose. The taste of such mixtures must be masked by citric acid. They are ingested in small quantities or are introduced into the stomach by nasal tube. When the acid hydrolysates with added tryptophan are administered by the intravenous or subcutaneous route, a well trained personnel is required, for patients must be carefully supervised because of the danger of thrombosis or violent febrile reactions. Satisfactory results were obtained with this treatment during the famine in Bengal in 1943 and also in many cases of severe hypoproteinemia among those liberated from German internment camps. Patients with extensive burns, children with athrepsia, patients in surgical shock or those with nitrogen deficiencies of various toxic or infectious origins benefit from the intravenous or subcutaneous injection of protein hydrolysates.

Cecal Volvulus.—Jakobsen in recent years has noted a pronounced increase in the number of cases of cecal volvulus in the surgical department of Ulleval Hospital in Oslo. The direct cause of this increased incidence may be found in the diet during the rationing of food in Norway. Coarser and darker bread, large quantities of kohlrabi and potatoes leave much residue and produce more gas. Various degrees of intestinal atony may result. In addition there may occur a reduction of the fat content in the mesenteries, a natural consequence of the general emaciation. The 5 cases reported showed a mesenterium ileocolicum commune. This anomaly is a necessary condition for the occurrence of cecal volvulus. The patients were 10, 13, 20, 30 and 80 years of age respectively. There were 3 male and 2 female patients. Diagnosis may be made by roentgenogram. Treatment consists in detorsion, emptying of the bowel through an intestinal tube inserted into the rectum, and fixation of the cecum in cases in which the bowel is not damaged. Resection in two stages, or sometimes in one stage, with ileotransversostomy is to be performed in cases in which the intestine is damaged.

Book Notices

Pulmonary Tuberculosis in the Adult: Its Fundamental Aspects. By Max Pinner, M.D. Chief, Division of Pulmonary Diseases, Montefiore Hospital for Chronic Diseases, New York. Fabrikoid. Price, $7.50. Pp. 579, with illustrations. Springfield, Ill.: Charles C Thomas, 1945.

In this book the author set out to demonstrate that it is possible for one writer to cover "in toto" the subject of pulmonary tuberculosis adequately and consistently. He contends that existing textbooks written by one author are inadequate in covering the theoretical aspects, while textbooks written by several authors lack consistency of presentation of the various phases of the subject. As a one author book it is an eminent success. To assemble it Dr. Pinner has made ample use of his command of the literature, his erudition and his gift for skilful presentation. The result is an excellent reference book on pulmonary tuberculosis. The book addresses itself chiefly to tuberculosis specialists. By inference these are mostly in need of instruction in what Pinner considers to be the fundamental aspects of their specialty. This instruction is given to them in this book of 550 pages, of which 350 deal with the pathology, immunology, pathogenesis, epidemiology and the physiologic implications of pulmonary tuberculosis. Of the remaining 200 pages, 60 are taken up by reviews of an imposing amount of literature. This leaves 150 pages to be devoted to the clinical phases of pulmonary tuberculosis, including its treatment. Most of the chapters are finished essays on their respective phases of the subject. They are so well rounded and concise presentations that they might well be published as separate essays. The author's preferences, individual inclinations and preoccupation are revealed in the size of these essays. Judging from the extent of the first few chapters, it would seem that the enterprise began as a presentation of the theoretical phases of pulmonary tuberculosis. Then a brief outline of the clinical aspects was added to complete the work. A discussion of the epidemiologic problems was attached to the end in what appears almost as an afterthought. Finally, much space was filled in between the chapters by the invention of a new feature, namely epigrammatic reviews of relevant literature. The book is thus made up of a collection of essays assembled in logical order to cover the whole subject. Every chapter is replete with data imparting a wealth of theoretical and factual knowledge. A large measure of consistency has been achieved throughout by carrying forward the author's favorite ideas with great skill.

The least that can be said of this work is that it represents an excellent exposition of the state of our knowledge of and concepts about pulmonary tuberculosis at this time. As such it was well worth the author's effort. Students of the disease will welcome the convenience of having assembled in this concise little volume a regular reference book to all phases of the subject. The general medical reader must find the volume topheavy with theory, affording but a small bird's eye view of the vast complexity of pulmonary tuberculosis as seen in clinical practice. The tuberculosis specialist too must question the term "fundamental" as applied to the immunologic, pathogenic and epidemiologic theories, particularly in the case of pulmonary tuberculosis. The most one can say is that it behooves every tuberculosis specialist to be familiar with our current ideas of the theoretical aspects of tuberculosis even though these are still in such a nebulous state as to have little if any bearing on our clinical thinking, let alone on the treatment of the disease. Even many of the older and newer concepts of the pathology never had the same bearing on the clinical interpretation in pulmonary tuberculosis as in other disease. For example, the pathologic theories which interpret Boeck sarcoid as a noncaseating form of tuberculosis has little bearing on the clinical evaluation of this elusive disease. Unfortunately, it is still true that a good practical textbook can be written on clinical pulmonary tuberculosis without consideration of the immunologic, pathogenic or epidemiologic theories.

On the whole, the book is probably the best of its kind published so far in the English language. Its success should be assured.

New Directions in Psychology: Toward Individual Happiness and Social Progress. By Samuel Lowy, M.D. Introduction by Herbert Read. Cloth. Price, $3. Pp. 194. New York: Emerson Books, Inc., 1945.

The author is a psychoanalyst practicing in England but originating in Czechoslovakia. He presents for lay people an application of psychoanalysis to social problems and terms the result a new social psychology. He does an excellent job of interpreting his technical knowledge and applying it to larger groups. The book is well written and interesting. However, the author has a peculiar propensity of using the abstract term "the state" as if it were an organization apart from "the people." To one familiar with Europeans it is apparent that the state means to the author something different than government means to Americans. He analyzes the neuroses gratified in members of the government of an authoritative state and the neuroses of those who willingly subjugate themselves to such a state and warns of the inherent dangers. He also believes that human weaklings must be guided and compelled by the state. One gets the impression that the author intellectually decries authoritative society but leans to it emotionally. The reviewer believes that understanding the emotional lives of sick individual persons does not help in analyzing a sick society.

The Management of the Mind. By Milton Harrington, M.D. Edited from posthumous manuscripts and notes by Ralph B. Winn, Ph.D. Cloth. Price, $3. Pp. 200. New York: Philosophical Library, 1945.

The author, who died in 1942, was a psychiatrist who held many positions during his lifetime and wrote "Wish Hunting in the Unconscious" and "The Biological Approach to the Problem of Abnormal Behavior." His widow and friends felt that the manuscript notes of this book should be edited and published as a memorial to his struggles and labors for a more scientific psychiatry. Under such circumstances a reviewer should be willing to overlook much for the sake of those who have idealized the author. But this he cannot honestly do. The contents are unscientific, consisting largely of musts, shoulds and must nots as directions to lay people who would understand themselves. There is no indication of any understanding of modern dynamic psychiatry or of the use of psychotherapy adapted to the treatment of mental or emotional disturbances. There is more criticism of others than constructive effort.

The Eternal Ones of the Dream: A Psychoanalytic Interpretation of Australian Myth and Ritual. By Géza Róheim, Ph.D. Cloth. Price, $4.50. Pp. 270, with illustrations. New York: International Universities Press, 1945.

This book is intended for anthropologists rather than for physicians. It contains great quantities of technical empirical details concerning primitive Australian culture. The author concludes: "Totemism as a social institution is a defense organized against the separation anxiety. . . . It represents our efforts to deal with the problem of growing up, aided by the illusion of an eternal future. In the eternal ones of the dream it is we who deny decay and aggression and object loss and who guard eternal youth and reunion with the mother. The old and decrepit men of the tribe become young and glorious once more." The book is intended for specialists rather than for the casually interested reader.

Needle in a Haystack: The Exciting Adventures of a Federal Narcotic Agent. By William J. Spillard as told to Pence James. Cloth. Price, $2.50. Pp. 193, with illustrations by Brinton Turkle. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1945.

William Spillard was a narcotic agent working out of the Chicago office of the Federal Narcotics Bureau, whose experiences led him into many contacts with criminal members of the medical profession who profited by violating the antinarcotic laws. He also had a great deal of experience with pedlers and addicts all over the country. With the aid of Pence James this experience has been made not only interesting but at times even amusing in its recounting.

Thy Health Shall Spring Forth: Readings in Religion and Health. By Russell L. Dicks. Cloth. Price. $1.25. Pp. 61. New York: Macmillan Company, 1945.

The chaplain of Wesley Memorial Hospital in Chicago presents here prayers and poems which have been helpful and stimulating to patients in the hospital. It is a book to give courage to people who are in the process of regaining health.

Queries and Minor Notes

DDT POISONING

To the Editor:—Approximately three weeks ago I had all the symptoms of hay fever, that is, swelling of the turbinates, profuse rhinorrhea and slight itching of the conjunctiva. The symptoms were most pronounced at night and disappeared during the day when I was at my office. A smear of the nasal secretion showed 12 per cent eosinophils. The blood smear showed 10 per cent eosinophils and a total white blood cell count of 13,000. The daily mouth temperature never exceeded 99 F. Having had no previous history of hay fever or other allergies, I was surprised at the sudden onset. A friend who heard me say that I had started using DDT spray at about the same time suggested that I try a patch test. This was positive, with erythema and a raised border, but no actual vesicles were seen. The erythema lasted for three days. The problem at present is how to desensitize myself and how to decontaminate the household. Any help you can give me will be appreciated

M.D., Texas.

To the Editor:—A man aged 54 suddenly had an attack of symptoms similar to those of insulin shock. He said that he felt himself going to pieces, feeling weak about the middle of his body, as though his shoulders were separated from his pelvis by an empty space, and with a subjective feeling of confusion rather than dizziness. I saw him two hours after the onset of his symptoms, during which time he had taken a glass of orange juice and some hot chocolate, with no alleviation. Also during this time he had taken care of a customer, lifting a heavy package and then taking a walk around the block to get fresh air. He said he used his will power to overcome his symptoms. The symptoms continued for several hours longer. There were no gastrointestinal symptoms. Fluoroscopic examination of the chest and taking of the pulse, an electrocardiogram and the blood pressure gave normal findings. The temperature was 97 F. In spite of his symptoms he was able to run up stairs in a lively manner. There was nothing in his food habits or other conditions of the past week which might account for the symptoms except that three days prior to the attack he had done a lot of spraying with a kerosene 5 per cent solution of DDT in a small room. His symptoms abated about eight hours after onset with no medication. On the following day he took his usual walk of several miles with his usual vigor and enjoyment and with no untoward results. Is this a case of DDT poisoning?

M.D., New York.

ANSWER.—1. Pure DDT (2,2 bis(p-chlorophenyl) 1,1,1 trichloroethane) does not cause irritation of the skin in either animals or man, nor is there definite evidence of a sensitizing effect on the skin or of production of other allergic manifestations such as asthma. However, certain solvents used in the preparation of DDT mists, sprays and aerosols are in themselves skin irritants if there is sufficient exposure. In addition, it should be pointed out that contamination of the skin with some of these solvents may cause such symptoms as paresthesias and anesthesias. The vapors of the solvents on inhalation, owing to their property of causing irritation of the mucous membranes, may cause the onset of asthmatic symptoms in a person who is asthmatic. The usually used 5 per cent DDT-95 per cent kerosene spray is a primary skin irritant, because of the kerosene. Therefore one would expect a positive patch test. Individuals vary in their skin reaction to kerosene; since this is not a sensitization phenomenon but a straight irritant action, desensitization need not be considered. As a rule the kerosene or other solvent used in the DDT insecticidal spray will evaporate from the surfaces sprayed after a period of a few weeks.

2. This is not a case of DDT poisoning. Although no cases of proved DDT poisoning in human beings apparently have occurred in the United States, it is probable that the same toxicologic picture as seen in animal experiments should prevail in human cases of DDT poisoning. The symptomatology of animals suffering from DDT poisoning is characterized by hyperexcitability, nervousness, generalized tremors, the clonic-tonic type of convulsions and coma, usually ending in death. These symptoms become manifest a few hours after exposure. The major exposure when using a 5 per cent DDT-95 per cent kerosene spray in an enclosed space is to the kerosene droplets and vapor. Any solvent suitable for dissolving DDT, which is very insoluble in water, is liable to cause irritation of the skin as a result of the same physicochemical properties which render it valuable as a DDT solvent. For the same reason they may cause irritation of the mucous membranes and in sufficient concentrations may cause systemic effects, such as nausea, vomiting, fatigue, headache and other nervous system manifestations. These symptoms usually become manifest very soon after exposure, and since the symptoms in the case cited occurred three days after exposure, it is further evidence that the spray which contained DDT was not the cause of the symptoms.

DIAGNOSIS OF UNDULANT FEVER

To the Editor:—This state has recently passed a law making undulant fever compensable as an industrial disease. There seems to be a good deal of confusion among doctors and in the literature as to how a diagnosis of undulant fever can be legally established. I realize that a positive blood culture will definitely establish the disease. The blood culture, however, is often negative even if repeated tests are taken. How reliable may agglutination tests be regarded? If an agglutination test is negative three weeks after the onset of illness, is it possible for the disease to still be undulant fever? How is an atypical agglutination of 1:50 or less to be regarded in the presence of clinical symptoms of the disease? Furthermore, how may an atypical agglutination of this titer be regarded in the absence of symptoms or in a routine check-up of a patient? A skin test is often positive in the presence of a negative agglutination test; may this be regarded as a positive diagnosis or just an indication that the disease may be undulant fever? The opsonocytophagic test is not always available.

M.D., Minnesota.

ANSWER.—In the absence of positive cultures the diagnosis of brucellosis cannot be established on either clinical criteria alone or on laboratory findings alone. All noncultural laboratory tests, if positive, must be interpreted only to the extent that a positive tuberculin test in an adult is interpreted: that at some past time the person has reacted to Brucella or derivatives. Therefore the diagnosis of existing disease depends on positive tests in conjunction with symptoms and signs that are compatible with brucellosis plus, preferably, historical evidence of exposure to this infection. Asymptomatic persons with positive tests who have never had previous injections of Brucella materials in any form have probably had the disease at some previous time. The disease may have been recognized or not, and it may have been wholly subclinical or inapparent. The reliabilities of the noncultural tests are fairly well known. They vary in relation to the stage of the disease at which they are applied. Agglutination tests are most reliable in the acute febrile stage, but even here they fail in about 10 per cent of cases. In subacute or chronic brucellosis positive agglutination tests occur in about 50 per cent of cases and the titers are usually 1:80 or lower. Opsonocytophagic tests give about 3 per cent of falsely negative reactions in either the acute or chronic forms. Brucellergen intradermal tests give about 10 per cent falsely negative reactions during the initial febrile stages and are slightly more reliable in the chronic disease. Diagnostic difficulties will become fewer if all three noncultural tests are applied in proper order to all persons suspected of having brucellosis, and especially if and when emphasis is placed not on this or that test or its degree of positivity but on test results considered in conjunction with clinical and epidemiologic findings.

TRANSMISSION OF TUBERCULOSIS FROM MOTHER TO INFANT

To the Editor:—Is it possible for a baby to contract tuberculosis from nursing its mother by milk alone? L. H. Brevard, M.D., Deeson, Miss.

ANSWER.—Tubercle bacilli in the milk is a rarity except when the mammary glands become tuberculous. Although they have been reported in the milk in the absence of demonstrable lesions of the mammary glands, in most instances there is no evidence that it was expressed under septic precautions. Moreover, there is always the possibility of tuberculous lesions existing in the mammary glands which cannot be detected by the usual examination. Although the mammary gland is not a common site for the development of tuberculosis, a good many unmistakable cases have been reported. Because of the prevalence of the bovine type of tubercle bacilli formerly reported in cow's milk, it was thought that these organisms were excreted by the mammary gland. However, later investigations revealed that the source of contamination was feces containing tubercle bacilli on the surface of the udder, which caused the contamination during the process of milking. In some instances the mammary gland itself was found to be tuberculous, and tubercle bacilli were eliminated through the milk.

From 5 to 10 per cent of the persons with advanced tuberculosis may have tubercle bacilli recovered from the blood stream on a single examination, and it is probable that 95 per cent of them have occasional showers of tubercle bacilli into the blood stream. However, the child of the tuberculous mother is well protected against them. They probably never enter the circulation of the fetus except when the placenta becomes tuberculous or some other disease breaks down its barrier effect. Moreover, tubercle bacilli in the blood stream do not enter the mother's milk except when lesions exist in the mammary gland itself. Despite the fact that the milk of a tuberculous mother whose mammary glands are normal does not contain tubercle bacilli, it is almost impossible for such a mother whose sputum is positive for tubercle bacilli to nurse her infant without causing infection.

NONSPECIFIC REACTIONS IN ROUTINE BLOOD TESTING FOR SYPHILIS

JOHN H. STOKES, M D
Professor of Dermatology and Syphilology, University of Pennsylvania School of Medicine; Director, Institute for the Control of Syphilis

FRED BOERNER, V.M D
Associate Professor of Clinical Bacteriology, University of Pennsylvania Graduate School of Medicine

A PARKER HITCHENS, M D
Visiting Professor of Public Health and Preventive Medicine, University of Pennsylvania School of Medicine

and

SONDRA NEMSER, M D
Physician in Charge, American Red Cross Blood Donor Center
Philadelphia

In a fourteen month period from December 1943 to February 1945 an investigation was sponsored by the Committee on Medical Research and the Venereal Disease Subcommittee of the National Research Council, supported by a grant from the Office of Scientific Research and Development, into the problem of the nonspecific positive (so-called "biologic false positive") reaction for syphilis. The bloods of Red Cross donors at the Philadelphia Blood Donor Center supplied the material, and the Institute for the Control of Syphilis at the University of Pennsylvania and the Graduate Hospital of the University of Pennsylvania conducted the case investigations. In all, 210,261 blood specimens were tested in a nine months period, and 79 of the donors showing definite positives ("unsatisfactory bloods") were subjected to subsequent critical clinical and laboratory examination. The studied series was enlarged to 98 cases by additional persons from private practice in whom possible nonspecific positive reactions for syphilis had been obtained largely in various forms of routine blood testing (premarital, industrial, general diagnostic practice).

The clinical histories and physical examinations were made by the staff of the Institute for the Control of Syphilis, no physician of less than two years' special experience in syphilis diagnosis being engaged in the work. All cases were subjected to still more experienced consultation and review. Additional laboratory tests were performed on simultaneously drawn specimens by the Boerner classification procedure at the Graduate Hospital of the University of Pennsylvania under the direction of Dr. Fred Boerner by a seven test "battery" at the Staten Island Research Center, United States Public Health Service, under the direction of Dr. John Mahoney, and in some cases by additional laboratories, including especially the Pennsylvania State Laboratory under Drs. Verner Nisbet and Claude Brown. A wide range of special clinical studies reinforced the physical examination (chest x-rays, cardiologic studies, slit lamp examinations and other work). Spinal fluid examinations, repetition of serologic tests, heterophile antibody reactions, brucellosis, typhoid agglutination tests and albumin-globulin estimations reinforced when indicated the preliminary survey. The results in each case were passed on repeatedly by a reviewing board[1] and a decision as to the diagnosis of syphilis or nonspecific serologic reaction was reached sometimes weeks and months after the case first came under study.

The results of this investigation of the serologic diagnosis of syphilis by routinized blood testing procedure were a surprise to the investigators and involve conclusions of interest to all physicians called on to evaluate blood tests for syphilis in general, special and industrial practice, and they have significance for public health and venereal disease control officers employing serologic tests for case finding purposes ("Wassermann barbeque"). The conclusions are here summarized, with recommendations, the detail of methods being published elsewhere.

Between January and September 1944, 489 out of 210,261 Red Cross donor blood specimens gave definite positive reactions to serologic tests for syphilis. This incidence of 0 23 per cent positives is substantially below even the low reported prevalence rates for the disease (0.5 per cent) in the Northwestern and Northeastern rural sections of this country as disclosed by serologic surveys. Certain selective factors were suspected, to wit: No donors were under age 20, 40 per cent were over 40 years; they were predominantly white (only 2,579 Negro donors); there were more females than males; the persons included were probably above the average in responsibility and conscience, and known sick persons and those having syphilis outright were probably largely excluded.

In the process of evaluation described, a diagnosis of syphilis was reached in three months in 69.2 per cent; in nonspecific positive cases in only 22 per cent. Of the nonsyphilitic positive cases, 78 per cent required more than three months for decision.

Only 40.5 per cent of the Red Cross donors with syphilis positive bloods were finally adjudged actually to have syphilis. The remainder, 59.5 per cent, were finally adjudged to have actual or probable biologic false or nonspecific positive reactions.

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the University of Pennsylvania

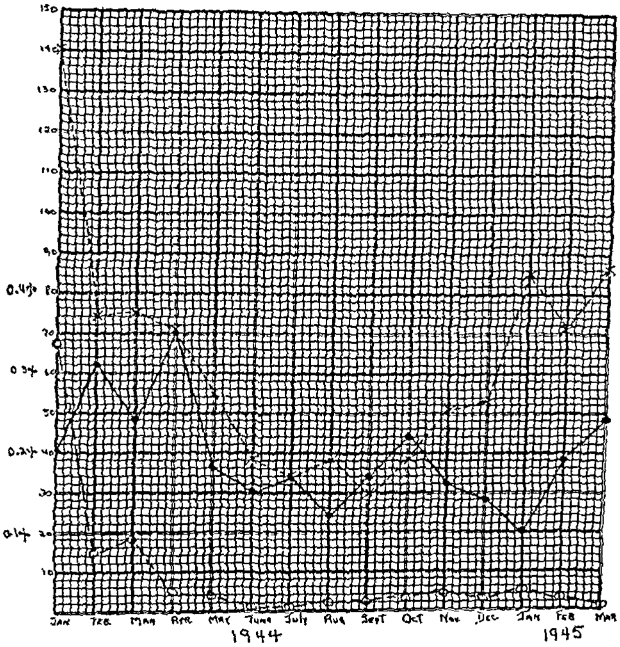
In addition to the responsible [illegible] participated actively in this study: Herman [illegible] R Ingraham Jr, M D, Louise E Tavs, M D, [illegible] D, Henry G. Morgan, Surgeon (R) U. S P [illegible], M D, Margaret J. Gerlach, M D, on behalf of the Institute for the Control of Syphilis; Verner Nisbet, M D, and Claude P Brown, M D, director and assistant director respectively, Pennsylvania State Laboratory, Philadelphia, and the United States Public Health Service Venereal Disease Research Laboratory, John F. Mahoney, medical director, United States Public Health Service, Staten Island, New York.

[1] This reviewing board, in addition to the responsible investigators, consisted of the collaborating clinicians and serologists enumerated in the title page footnote.

Among possible selective influences in the incidence of biologic false positive, that of season was suspected. Two recognized disease sources of nonspecific positives, pneumonia and other respiratory tract infections, are known sources of nonspecific positives. The accompanying chart shows a parallel tendency in the incidence curves of pneumonia (deaths) and the percentage (by months) of nonspecific positiveness. The influenza parallelism is less definite (no second peak). Allowance must be made in all estimates for the difficulty of making a "diagnosis" of nonspecific positive or "biologic false positive reactor" in any given case. Only 3 cases in the series were adjudged to be technical false positives.

THE CLINICAL HISTORY AND EXAMINATION

The clinician's history and examination of this group as a means of differentiating syphilis from nonsyphilitic was, in contrast to its usual claims to "court of last resort" status, disappointing. The final resort was perforce too often serologic. With respect to history, there was a slight preponderance of recent vaccination, upper respiratory infection, inoculations and recent febrile illness and infection in nonspecific positive cases. A significant clue was the preponderating "serologic discord" or history of conflicting serologic reports in nonspecific positives. A history of syphilis in the family or of primary and secondary manifestations in the patient was of little or no value.



Possible influence of season and epidemic infection on incidence of nonspecific positive blood tests. Broken line with x's, pneumonia death rate per hundred thousand, Middle Atlantic states; dashes with circles, influenza case rate per hundred [illegible] Middle Atlantic states; solid line with black dots, incidence of [illegible] ositive reports) in donated bloods (in percentage [illegible] that the peak of incidence of pneumonia deaths [illegible] (upper respiratory tract disease known or sus[illegible] "biologic false positives") corresponds fairly well to peaks [illegible] dence of nonspecific positives among Red Cross blood donors. There is even a one month lag, which has already been recognized as occurring in nonspecific positives due to respiratory tract disease.

In the physical examinatioin for "landmarks" of syphilis and "suspicion arousers," the yield of definitive findings was small, though better than from the history.

Not only were the symptoms and signs of the presence of syphilis equivocal, often unconvincing and hardly to be distinguished from signs and symptoms present in those ultimately adjudged after painful debate to be the victims of nonspecific positive serologic reaction, but sequences strongly supporting recognized causes of nonspecific positive reaction in accordance with our present knowledge of the subject were disappointingly few and far between.

The clinicians concerned, who had good reason to regard themselves as anything but "duds" in the field, soon learned the extent to which even experts may differ on points of physical examination particularly, involved, as suspicion arousers or diagnostic items, in the identification of syphilis. Opinion on the level of the liver, the presence or absence of true enlargement, the configuration of teeth and of bones, the shape and height of the palate, the interpretation of pupillary reactions and the interpretation of murmurs over the precordium were fertile fields of disagreement among both examiners and consultants.

In the physical examination, as might be expected, evidence for the presence of syphilis was found largely in examination of the eyes (including slit lamp study for vascularization of the corneas), characteristic teeth in congenital syphilis, the skeletal changes of congenital syphilis, the facies and the reflexes. It was quite characteristic of this investigation, as of private consultant practice at the present time, that congenital syphilis and neurosyphilis are the two chief clinical types uncovered by mass serologic testing.

SPECIAL STUDIES

The special studies made in response to apparent indications in the individual case (other than special serologic test procedures for syphilis) had a rather small positive yield. The high points are as follows:

Of 50 spinal fluids examined, 6 representing separate cases were abnormal.

Heterophile tests were performed a number of times in some cases.

In cases of syphilis none were over 1:112, 4 of 34 were suggestive (1:112), 12 per cent, and none were presumptive (1:224).

In nonspecific positive cases 11 of 58 were suggestive (1:112 and over), 19 per cent, and 6 of 58 were presumptive (1:224 and over), 10 per cent.

Radiographic examination of the chest showed abnormalities of some type in 12 of 41 cases, including 1 of active tuberculosis and 3 cases of pneumonitis; no virus pneumonia. Of 11 syphilitic cases examined, 3 showed abnormalities of the chest roentgenogram. Of 30 nonspecific positive cases examined, 9 showed abnormalities.

The special consultant on congenital stigmas identified 10 suggestive cases in 23 examinations. Only 6 such diagnoses (congenital syphilis) were finally accepted.

The special family study identified 1 syphilitic of 4; eye examination identified 4 syphilitic in 9 cases examined; the cardiovascular examination was suggestive in 3, and only 1 finally closed as syphilis.

The question as to whether every person who has a confirmed and persistent strongly positive serologic reaction should have a spinal fluid examination can, we feel, be answered with a qualified negative. If the course of the case under observation tends to support the suspicion that the serologic positive is syphilitic in origin, a spinal fluid examination is certainly indicated, but if the decline of the originally positive or doubtful blood to negative is reasonably prompt on weekly repetition, we feel that in the complete absence of clinical signs of syphilis the spinal fluid examination need not be insisted on. The yield of neurosyphilis in this material was small, hardly more than 10 per cent of the fluids examined being abnormal.

It is probable that, on the one hand, the infections of the nasorespiratory tract giving rise to nonspecific serologic reaction are either prostrating and severe and hence do not appear in this material at the time it comes in for examination or are perhaps minor affairs in predisposed reactors or the results of highly specific infection complications.

The identification of congenital syphilis by the special consultant has well illustrated the uncertainties which minor abnormalities of no primary significance in themselves but "uncomfortable" when viewed in the aggregate arouse as to the status of an individual with no other explanation for his serologic picture; they give rise to the suspicion that the patient may have a mild case of congenital infection late in its course toward spontaneous recovery. It may be said, however, that physicians can afford to familiarize themselves better with the typical mulberry or Moon molar, equally with the hutchinsonian incisor, for this is an important and often surprising aid in diagnosis. The proper lighting of the face for the interpretation of the facies and for the presence of rhagades is also important. The tibia, like the liver, is a field for chronic difference of opinion among "experts" in the borderline cases.

THE SEROLOGIC STUDIES

The Boerner classification procedure, devised for the purposes of this study, is essentially an interpretation of simultaneously performed, exceptionally sensitive tests for the detection of flocculating and complement fixing reagin. The details of the technic are in process of publication.[2]

In the system of classification employed in the Boerner procedure, those reported as giving serologic reactions in groups 3 and 4 are overwhelmingly likely to have syphilis; those consistently reported in groups 1 and 2 are very unlikely to have syphilis.

In the Boerner classification procedure a consistently high titer of reagin is maintained from beginning to end of the serologic investigation in the syphilitic, while in nonspecific (biologic false) positives a low titer is maintained consistently from start to finish in approximately the same proportion.

In appraising the multiple test "battery" as a checking procedure as carried out by Dr. Mahoney, an outright comparison of the Mazzini, Hinton, Eagle, Kline exclusion, Kline diagnostic, Kahn and Kolmer procedures cannot be offered.

The very high rating of the Mazzini test in the detection of syphilis and also that of the Kline exclusion test (of which it might, of course, be expected), and the Kahn, could be recognized. On the other hand, all of the precipitation tests run quite high in the proportion of strong positives and of strong and moderate positives obtained in nonspecific blood serums. The Kolmer complement fixation (as performed in Mahoney's laboratory), on the other hand, while less sensitive in the detection of syphilis, is a notably safer resort than any of the precipitation tests except the Kline diagnostic for the avoidance of strong positives in the nonspecific field. The performance of the Kline diagnostic test quite closely resembles that of the Kolmer. Broadly speaking, then, one would be inclined to infer that a precipitation test should either not be used or should be paralleled by a dependable and sensitive complement fixation procedure in any and every serologic survey of a mass material in which nonspecific positives may appear.

In a detailed comparison within the Boerner classification procedure, of both the Lund flocculation and the Boerner fixation of complement tests, it was even more clearly evident that a highly sensitive flocculation or precipitation test must not be used alone or as a screen procedure unless one wishes to have a harvest of nonspecific positives. This now inescapable fact is one to which authorities having power to select a syphilis blood testing procedure should pay heed. A test such as the Lund will, as compared with a complement fixation test such as the Boerner-Lukens, allow only 4 syphilitic persons to escape diagnosis to be sure, instead of 16; on the other hand, the price paid for this superior sensitivity is the difference between 123 nonspecific positives by flocculation and 44 by complement fixation; in other words, 79 persons "unjustly" suspected of having syphilis. The Boerner-Lukens fixation of complement procedure gives only 32 strong positive tests in the nonspecific group as against 93 with the Lund precipitation. When, however, the two procedures are combined for interpretation in accordance with the Boerner classification, the results are superior in accuracy and certainly in interpretability by the practitioner. As judged by all criteria, clinical and laboratory, in this study, syphilis can be separated from nonspecific positiveness with a high proportion of correctness by the Boerner classification. It is of course conceded that a specific test for syphilitic reagin or for the nonsyphilitic reagin, if such exists, would be more satisfactory and dependable, if and when such a procedure is devised. On the other hand, with the Boerner procedure in this material, only 29 of a total of 242 nonspecific tests yielded positive results, and 213 were negative or doubtful. Of the tests on the serums of persons diagnosed as syphilitic, 114 were positive and only 16 were negative or doubtful.

THE DECISION AS TO WHETHER OR NOT A PERSON HAS SYPHILIS

It will be apparent that within the field of this somewhat selected material this study does not solve all the difficulties intrinsic to both the identification and the exclusion of syphilis in any individual case. It indicates, however, quite clearly that a disconcerting proportion of the serologic crop obtained by a routine test procedure on a large scale sampling of blood in a population group will yield a high proportion of nonspecific positives. Unquestionably, large numbers of persons have, both before and during the era of the "serologic barbeque" been subjected to treatment for nonsyphilitic or, rather, nonexistent "syphilitic" infection. The validity of syphilis prevalence figures in current use, as obtained from the premarital and antepartum syphilis-uncovering programs, Selective Service serologic data and so on may perhaps require reexamination. While the diagnosis of syphilis by history and physical examination may be an important aid in the early outspoken manifestations of the infectious period of the disease, these aids lose much of their worth as the infection passes into latency and even into the period of late manifestations. The discouraged physician and even the clinical expert will therefore be forced to lean on serologic procedure for the identification of the disease. Our own study, for example, furnished us with repeated warnings and to some extent with evidence of the inevitability of this leaning on the serologic results for diagnosis in the absence of any other basis for diagnosis. The clinician may expect to identify, if he is sufficiently expert, indubitable symptoms and signs of the disease in a proportion of cases of seropositiveness dependent on the type of material with which he is dealing. Too often he will throw a weight of suspicion disappointingly small and based on slender and debatable evidence into the scales with the serologic test. He will not be able to diagnose syphilis by negative exclusion ("It's not anything else, so it must be syphilis"), that is, by failing to find a recognized cause for a nonspecific positive serologic reaction. At times he may even be compelled to "diagnose" syphilis and to advise its treatment for a patient who is so consistent a nonspecific positive reactor that one cannot trust the disproof of syphilis and must therefore consider it unsafe to believe that the person does not have the specific disease. With the advent of penicillin perhaps such diagnostic escapes will be too easily accepted and practiced.

---

[2] Boerner, Fred: (1) A Quantitative Macro Flocculation Test for the Diagnosis of Syphilis; (2) A Quantitative Fixation of Complement Test for the Diagnosis of Syphilis, Echinococcus Disease, Malaria, Bacterial and Other Diseases; (3) A Method for Grouping and Classifying Serologic Reactions for Syphilis, to be published in the American Journal of Clinical Pathology and/or the Technical Supplement thereto.

The outright diagnosis of a nonspecific positive at the present time is laboratory rather than clinical—a consistent weak or doubtful positive reaction, its decline to negative within a "reasonable" time, currently estimated in the literature as approximately three months. A suggestion but certainly not a presumption in favor of nonspecific positiveness, in the majority of cases such as ours, may be raised by a record of intercurrent or recently antecedent infection, especially of the upper respiratory tract, accompanied by fever. The special test procedures to determine the character and location of such infection will usually be applied too late to be of material value in sustaining a diagnosis of nonspecific positive reaction. They therefore, at best, establish little more than a suspicion arousing type of reaction in the mind of the consultant, and the final decision again falls to the serologic test procedure and in the future, let us hope, to a specific physicochemical test for nonspecificity.

The serologic warnings of nonspecificity are again (1) consistent weak or doubtful positiveness, punctuated with occasional high titer precipitation reactions, (2) serologic fluctuation and discord, i. e. disagreement between tests and among laboratories, and (3) negative complement fixation with positive flocculation reaction. For the simplified and yet increasingly accurate differentiation of syphilitic from nonspecific positive serums on repeated testing, by a procedure easily available to well equipped serologic laboratories, this investigation offers the Boerner classification procedure as deserving of widespread trial even though it may presently be overtaken by a contribution from the physical chemists.

SOME PRINCIPLES SUGGESTED FOR ROUTINE BLOOD TESTING PROCEDURES

1. Mere routine blood serologic testing, without examination or questioning, will certainly lead to a proportion of nonspecific positives that will be expensive and serious for the individuals concerned and a source of error in statistical evaluation. The nonspecific positives obtained may run as high as 50 per cent, depending on the selection of case material, on the serologic procedures employed and on the rating given partial positives.

2. The best laboratories will give nonspecific positive serologic reports, but they will be fewer if a complement fixation technic is used and more easily interpreted if a quantitative precipitation test is matched against a quantitative fixation of complement test, as in the Boerner classification procedure.

3. The drawing of blood for serologic testing should be preceded or accompanied by:

(a) Questions:

Have you had or been treated for syphilis or gonorrhea?

Ask again and again.

Have you had malaria?

Have you had within a month a fever, cold, grip, pneumonia, severe sore throat?

Have you had any preventive inoculations within three months (tetanus, typhoid, smallpox vaccination)?

Have you had blood tests before? Results?

(b) At least a once over physical inspection:

Pupils.

Rashes (semistripped or stripped).

Oral mucosae and teeth.

Genitalia if possible or indicated.

Tibias.

Signs of intercurrent infection.

(c) Temperature, pulse, respiration. Auscultation of heart and lungs if above normal.

4. Nonspecific positives may be suspected if:

(a) There is a weak positive or doubtful serologic test result.

(b) There is a conflict between precipitation and complement fixation results.

(c) Even though a repetition is positive, the titer remains low and is fluctuant.

(d) There is a decline in titer to negative on weekly tests for one to three months, without treatment.

5. A syphilitic positive should be suspected if:

(a) The original and subsequent reaction are persistently of high or even low titer.

(b) The repetitions confirm each other over a three months period.

(c) There is clinical or anamnestic evidence of positive weight.

(d) The spinal fluid, after the aforementioned blood checks, is definitely abnormal, not alone with respect to serologic tests.

CONCLUSIONS

1. Examination of 210,261 Red Cross donor bloods disclosed 489, or 0.23 per cent, "unsatisfactory"—that is, seropositive in tests for syphilis (Kahn, Kolmer check).

2. Of 79 essentially unselected donors with positive serologic tests submitted to further extended clinical, serologic and other special studies, only 40.5 per cent were finally adjudged by a reviewing board to have syphilis.

3. The time required for a decision was less than three months in 69.2 per cent of the syphilitic, more than three months in 78 per cent of the nonspecific positives.

4. A suggestion of seasonal infection influence on seropositiveness appeared in the Red Cross material. Serologic surveys should be run in summer.

5. History and physical examination contributed little to differentiation of syphilitic and nonspecific positives.

6. Sharply defined clinical evidence supporting the nonspecific diagnosis is almost equally difficult to elicit.

7. Asymptomatic neurosyphilis and congenital syphilis were the two types of the disease, other than monosymptomatic seropositive latency, uncovered.

8. The detection of previously undiagnosed syphilis, now latent, in present knowledge is inevitably serologic.

9. Precipitation tests tend to be unreliable unless matched against complement fixation tests.

10. The syphilitic positive is a high titer, consistent positive on multiple repetition, precipitation and complement fixation confirming each other.

11. The nonspecific test is of low reagin titer, usually weak positive or doubtful but fluctuant, sometimes with strong positives; inconsistent as between precipitation and complement fixation, tending to be more positive in the former than the latter; tending toward negative within a three months period on weekly repetition.

12. The Boerner classification procedure offers an accessible method of interpreting serologic reactions.

13. Doubtful cases should be kept under prolonged observation. Even at the end of a year the diagnosis may still be undetermined.

ALKALI TREATMENT OF METHYL ALCOHOL POISONING

COMMANDER W. B. CHEW (MC), U.S.N.R.
COMMANDER E. H. BERGER (MC), U.S.N.R.
CAPTAIN O. A. BRINES (MC), U.S.N.R.
and
CAPTAIN M. J. CAPRON (MC), U.S.N.R.

For sixty years methyl alcohol has been recognized as a poison causing either death or blindness in a large percentage of cases. Recently we had under our care two groups of patients totaling 31 who had partaken of mixtures containing methyl alcohol and who showed clinical evidence of methyl alcohol poisoning. Of this group 5 died within three hours after admission to the hospital. The rest recovered and were returned to duty. It is our purpose to present the clinical and pathologic data found in this group and to demonstrate the value of the use of alkali therapy in the treatment of methyl alcohol poisoning.

In 1880 methyl alcohol was found to be toxic regardless of the port of entry, including the skin. The amount of methyl alcohol necessary to poison was found to vary considerably, depending on the tolerance of the individual. One man drank 1 pint of 10 per cent mixture daily without producing ill effects.[1] A single 4 cc. dose of methyl alcohol was a toxic dose in another instance.[2] It is recorded that 10 cc.,[3] 30 to 60 cc. and 180 to 240 cc. repeatedly caused death.[4] On the other hand much larger amounts have been taken without causing temporary or permanent injury.

It is commonly considered that methyl alcohol has a predilection for the retina and optic nerves. Degeneration takes place in the ganglion cells of the retina as well as nerve tissue elsewhere in the central nervous system. With this there is engorgement of the capillaries and edema. Furthermore, it has been shown both by postmortem and by experimental studies that methyl alcohol may cause acute parenchymatous degeneration of the kidneys, liver, heart and other organs.

The action of methyl alcohol, although slower, resembles ethyl alcohol in that it can produce intoxication. Ethyl alcohol is oxidized readily and excreted within twenty-four hours, whereas methyl alcohol may be present in the system for days. Methyl alcohol is not fully oxidized in the body but is broken down into formic acid and formaldehyde. Formic acid has been found in abnormal amounts eight days after ingestion[5] of methyl alcohol. Experimentally, formates were found in the urine of dogs five to six days after the administration of methyl alcohol. The intoxication upsets metabolism so that excessive amounts of lactic and other organic acids are excreted in the urine for days.[6] This disturbance commonly results in a profound acidosis which has long been recognized but not fully appreciated.[7]

The symptoms of methyl alcohol intoxication are usually delayed for nine to thirty-six hours, during which time an individual may continue to carry on. Suddenly weakness, headache, nausea and epigastric distress may appear, associated with dimness of vision. Blindness may follow rapidly, with an increase in the gravity of the condition. Within a few hours, dyspnea of the Kussmaul type and cyanosis may appear, resulting in death within an hour or so. If death does not supervene, coma may last for several days before improvement occurs. Permanent blindness is then a frequent result.

The diagnosis is usually made on the presence of a toxic state following ingestion of an alcoholic beverage, or other exposure to methyl alcohol, in which impairment of vision exists with dilatation of the pupils. Methyl alcohol and its derivatives can be found in the urine or gastric contents in abnormal amounts.

The treatment has consisted for the most part in the administration of fluids, gastric lavage and purgatives. The profound acidosis present in methyl alcohol poisoning prompts some to administer alkali with good results[8] That this treatment is successful is amply substantiated by our results.

CLINICAL DATA

Table 1 presents clinical data on each of the 26 patients who recovered. The estimated maximum amount of methyl alcohol ingested was 540 cc. The minimum was 90 cc. The average amount was 222 cc. In addition many also drank beer in amounts ranging from none to 21 cans.

The symptoms of intoxication came on in about one hour in 1 case, while they did not appear for about forty hours in another. The average time from the first ingestion of methyl alcohol until the appearance of symptoms of intoxication was fifteen hours. Nausea, vomiting and abdominal cramps commonly occurred. The pupils of many were dilated. Fifteen patients reported blurring and dimness of vision. Several of these patients also had yellow vision. Eighteen had definite ophthalmoscopic findings in the fundus. This was chiefly congestion of the optic disk, and edema of the disk and the immediately adjacent zone of the retina. It is also noteworthy that 8 of the patients who had no visual symptoms did have objective changes in the ocular fundi. Mental symptoms such as dizziness and amnesia were commonly present. One patient was in coma about twelve hours yet lived. Those who were severely ill had dyspnea of the Kussmaul type. The respirations of the patients who died became rapid and shallow as coma deepened, with intense cyanosis, ending in respiratory failure. Treatment was instituted in our series of cases from eleven to thirty-seven hours after the first ingestion of methyl alcohol. The average time interval was twenty-seven hours.

Table 2 presents data regarding the carbon dioxide combining power of the plasma in 26 cases and data regarding treatment. The carbon dioxide combining

---

A preliminary report appeared in the Pacific Fleet Medical News **1**: 1-5 (May) 1945.

power was diminished in all but 1 instance. The highest value on admission was 55, the lowest 12 and the average 26 volumes per cent. There was no correlation between the value of the carbon dioxide combining power and the amount of methyl alcohol ingested. Two patients had values of 12 volumes per cent. One had taken about 360 cc. of alcohol; the other had taken but 12 cc. As expected, those whose clinical condition was the worst had the lowest levels of alkali reserve and vice versa. Dyspnea was observed chiefly in those in whom acidosis was most pronounced.

Treatment was directed primarily toward overcoming the acidosis. Alkali was given intravenously in the form of ⅙ molar sodium r-lactate in isotonic solution of three chlorides. The amount given was guided by repeated plasma bicarbonate determination in conjunction with clinical indications. None was given in a few cases, while as much as 640 cc. of molar sodium r-lactate solution was given in another, within the first twenty-four hours. The average amount given during the first twenty-four hours was 291 cc. In addition, sodium bicarbonate was given by mouth or by gavage, starting with a dosage of 4 Gm. every fifteen minutes. The total amounts of sodium bicarbonate administered during the first twenty-four hours varied from 12 to 100 Gm. The average amount was 51.6 Gm. The total alkali administered both intravenously and by mouth during the first twenty-four hours varied between 16 and 140 Gm., calculated as sodium bicarbonate. The average was 73.8 Gm. There was a rough correlation between the original level of the carbon dioxide combining power of the blood and the amount of alkali given during the first twenty-four hours. In addition, fluids were forced by mouth.

Whisky was given in 1 ounce doses (30 cc.) every four hours for a day or two. The eyes were protected from the light.

The response to treatment was prompt in most cases, as indicated by both clinical and laboratory criteria. Within a few hours dyspnea, nausea, cramps and mental symptoms abated and there was a progressive rise of plasma bicarbonate. It was not possible to determine the plasma bicarbonate at short intervals throughout the period of treatment on this large group of patients. However, in none of the cases was the carbon dioxide combining power below 35 volumes per cent, fourteen hours after treatment was started.

The improvement of eye changes under this treatment was particularly gratifying. Within twenty-four hours subjective blurring of vision had cleared in many of the cases. Notable diminution of congestion and edema of the optic disk and retina occurred within two to three days. At the time of discharge from the hospital, which averaged two weeks, all but 4 patients had central vision as good as that previously recorded in their health records, and their fundi appeared normal. These 4 showed a slight degree of retinal edema and had a slight diminution of central vision, insufficient to interfere with their duties. They also had contraction of the peripheral fields of vision and 1 had a large cecocentral scotoma in each eye. In the three months since discharge 2 of these 4 patients have regained apparently normal vision and fundi. Both of the others have some pallor of the temporal sides of the disks. One has concentric contraction of the visual fields and the other still has large cecocentral scotomas which have not changed since his discharge from the hospital. Central vision is not seriously affected in either case.

REPORT ON FIVE DEATHS

There were five deaths. Four of these men were comatose and critically ill on admission to the hospital. One was conscious but lapsed into coma very shortly. They all were intensely cyanotic and had pronounced respiratory embarrassment. Response to therapy was nil and they died in respiratory failure within three hours after admission. In each case heart action persisted for some time after respirations ceased.

Necropsies were performed in all 5 cases approximately forty-eight hours after death.

On inspection a characteristic pinkish red postmortem lividity was consistently present in all cases, involving chiefly the face, neck, shoulders, abdomen and thighs. This was probably due to the presence of an alteration product of hemoglobin similar to carboxyhemoglobin (HbCO) or methylhemoglobin ($HbCH_3$). There was cyanosis of the fingers and finger nails in all cases.

Cranial Cavity.—In all cases there was hyperemia of the pia-arachnoid but only a moderate accumulation of spinal fluid in the subarachnoid space. The brains weighed between 1,430 and 1,570 Gm., averaging 1,490 Gm., which represents an average increase of at least 100 Gm. above the usual brain weight. The ventricles were normal. and there were no parenchymal lesions. Microscopically there was evidence of cerebral edema in the form of widening of the perivascular and perineuronal spaces, loosening of the brain substance generally and swelling of glial cells. There was no evidence of hemorrhage or devastation necrosis.

Thoracic Cavity.—There was no accumulation of fluid in the pleural cavities in any case. All mediastinal structures were normal. There was moderate to severe hypostatic congestion of the lungs in all cases, and the weight of the lungs varied from 700 to 1,100 Gm.

Cardiovascular System.—The heart and great blood vessels were essentially normal in each case. The blood was uniformrly unclotted but was dark colored and not cherry red as it is sometimes described in this type of case.

Abdominal Cavity.—There was no increase of peritoneal fluid. All peritoneal surfaces were normal, and all abdominal organs appeared normal. The livers were uniformly paler than normal and weighed between 1,580 and 2,030 Gm., the average being 1,710 Gm., constituting some fatty infiltration in the form of small droplets; changes usually attributed to anoxia were present. Necrosis was not observed. The gastric contents were fluid and possessed no significant odor. The mucosa was hyperemic in all cases but 1. Other abdominal organs were normal.

Adrenals.—There was no necrosis or hemorrhage.

Urogenital System.—The kidneys were essentially normal except for moderate passive congestion. The urinary bladder in each case was normal except for mild mucosal hyperemia.

Anatomic Summary.—Examination revealed (1) cerebral edema, (2) hypostatic pulmonary congestion, (3) fatty infiltration of the liver and (4) passive congestion of all organs.

Toxicologic Examination.—Through the courtesy of Lieut. Comdr. L. J. Goldwater (MC), U.S.N.R., officer in charge of the Industrial Health Laboratory, Navy number 128, the following chemical examinations were performed:

Specimens of brain tissue were removed in each necropsy. Their methyl alcohol content ranged between 9.7 and 1.5 per cent by weight—sufficient in all cases to cause death.

A sample of fluid submitted and labeled "from bottle or canteen in barracks D" was found to be composed of practically pure methyl alcohol.

COMMENT

This group of cases demonstrates that the individual susceptibility to methyl alcohol varies considerably. There was no correlation between the amount ingested and the clinical picture, the eye changes or the level of the plasma carbon dioxide combining power.

It is important to appreciate that the action of methyl alcohol is slow. It produces a profound alteration in metabolism resulting in acidosis. Methanol or its products are not selective in their action, i. e., on the optic nerve, but affect many vital organs.

The treatment of this acidosis by sodium bicarbonate has been reported before; however, its importance has not been fully appreciated. Recently 2 men were admitted to this hospital who were in a party of 4 who drank "Ditto fluid" containing methyl alcohol about three weeks previously. Two had died. The remaining 2 have very little vision as the result of atrophy of the optic nerve. No alkali therapy was given, according to their records.

Whisky was given to our patients because Røe[9] expressed the opinion that ethyl alcohol promotes the displacement of methyl alcohol from its intracellular attachments and therefore was considered beneficial in the early treatment of methyl alcohol poisoning. There was no correlation between the relative amount of beer or whisky ingested and the clinical condition of our cases, or their response to treatment.

TREATMENT

In view of the excellent results effected in our cases, the following treatment is recommended for methyl alcohol poisoning. When the patient is in shock and respiratory failure is imminent, nikethamide intravenously and oxygen in addition to the other general measures should be used. Immediate application of treatment is necessary, may be life saving and may prevent irreparable visual damage. Prompt elimination of the acidosis, we feel, is essential in the treatment of methyl alcohol poisoning.

1. Draw blood for the plasma carbon dioxide combining power. The plasma carbon dioxide may be down to 10 volumes per cent.

2. Then administer alkali immediately as follows:

(a) Put four 40 cc. ampules of sodium r-lactate molar solution into 1 liter of isotonic solution of three chlorides and give intravenously.[10]

(b) Give 4 Gm. of sodium bicarbonate by mouth every fifteen minutes for four doses. If the patient is comatose, give it by a stomach tube.

3. Following administration of the aforementioned amount of alkali, recheck the plasma bicarbonate. Then immediately repeat the administration of the sodium r-lactate isotonic solution of three chlorides and the sodium bicarbonate by mouth as outlined. It has been our experience that the course of alkali outlined will have to be repeated three or four times consecutively to result in the elevation of the plasma carbon dioxide combining power from 10 to 20 volumes per cent to 40 to 50 volumes per cent. When this point is reached it may be checked twice daily until recovery is complete. If facilities are not available for the estimation of plasma bicarbonate, the reaction of the urine may be used as a guide to the administration of alkali. In our cases we used this reaction to regulate the continued administration of sodium bicarbonate after the plasma bicarbonate had returned to nearly normal values. At that time we tested each voiding of urine and gave 2 Gm. of sodium bicarbonate each hour while the urine was below a p_H of 7.0. The same dose was given every two hours when the urine reached a p_H of 7.0. When the urine became alkaline to phenolsulfonphthalein (p_H 7.8) the administration of soda was suspended. This scheme was continued for four or five days.

4. It is important to keep the eyes covered until all visual and retinal changes have disappeared.

CONCLUSION

The essential principle in the treatment of these cases was the correction of acidosis.

Twenty-six patients recovered and were returned to duty. All but 4 had complete restoration of vision at the time of discharge from the hospital.

---

[10] If sodium lactate solution is not immediately available, 5 per cent sodium bicarbonate freshly and properly prepared for intravenous use may be given in doses of 250 cc This amount of alkali is equivalent to four ampules of the molar sodium r lactate solution The lactate solution is preferable, however, since it yields the sodium ion more slowly into the system and thereby lessens the possibility of an uncompensated alkalosis

---

Extradural Hemorrhage.—A finding of value in the diagnosis and localization of an extradural hemorrhage is a dilated pupil which does not react to light or accommodation. This dilated fixed (Hutchinson's) pupil, with or without other signs of paralysis of the third nerve, is always on the same side as the clot and it is due to compression of the third nerve by the hippocampal gyrus, which has been herniated over the free edge of the tentorium. This herniation can readily be demonstrated at necropsy and has been experimentally produced by Cone and Reid It must be remembered that mere inequality of pupils or a dilated pupil which reacts to light has no localizing value.—Merritt, H. Houston: Diagnostic Considerations in Patients with Head Injury, in Trauma of the Central Nervous System, Baltimore, Williams & Wilkins Company, 1945.

THE IN VITRO ACTION OF STREPTOMYCIN ON BACTERIA

C. W. BUGGS, Ph.D., BERNICE BRONSTEIN, M.S.
JOHN WINSLOW HIRSHFELD, M.D.
and
MATTHEW A PILLING, M.D.
Detroit

Streptomycin is effective against a variety of gram negative and gram positive bacteria both in vivo and in vitro.[1] However, its rational use in the treatment of disease must be preceded by an evaluation of dose intervals and sizes with a determination of bacterial susceptibility to its action. There are definite in vitro differences in the sensitivity of bacteria to streptomycin and within a given species strains may be found varying from extreme susceptibility to high resistance. As the blood concentration of streptomycin reaches a peak shortly after parenteral injection and then gradually falls to zero[2] it becomes necessary, for rational therapy, to determine whether a sufficiently high blood concentration is being maintained with reference to the sensitivity of the bacteria isolated from the patient. In many cases it may be found that a smaller dose or a longer interval between doses is sufficient to maintain a blood concentration which is more than ample to inhibit the in vitro growth of the invading bacterium. On the other hand, blood level and sensitivity determinations may indicate that a larger dose given at more frequent intervals is needed.

Our purpose in this communication is to report (1) the sensitivities of several species of bacteria to streptomycin, (2) to correlate these sensitivities with the serum concentrations of streptomycin that may be maintained in patients receiving the drug and (3) to determine whether the bacteria investigated developed a resistance to streptomycin in vivo.

SOURCES OF THE BACTERIA INVESTIGATED

The bacteria studied were isolated from 38 patients with various types of infections, among which were peritonitis, thoracic empyema, septicemia, infected wounds and burns, urinary tract infections and pelvic abscesses. Urine or pus from each case was cultured before and at intervals during streptomycin treatment and the organisms present were isolated in pure culture. Complete identification of all bacteria was not made, this being limited to Proteus vulgaris, Escherichia coli, Aerobacter aerogenes, Pseudomonas aeruginosa, alpha and beta hemolytic streptococci and the staphylococci. Other organisms were grouped according to their

morphology, gram staining reaction and oxygen requirement. After the aerobes were obtained in pure culture they were screened for their sensitivity to streptomycin, following which their sensitivity over a narrower range was determined. The action of streptomycin on the anaerobes was not tested.

SCREENING FOR THE APPROXIMATE SENSITIVITY TO STREPTOMYCIN

An aqueous solution of streptomycin [3] having a concentration of 448 S [4] units was prepared from a weighed amount of the dry product. Twofold serial dilutions of this solution were made in nutrient broth, using 0.4 cc. of the streptomycin solution. The dilution was carried through thirteen tubes. An inoculum of 0.3 cc. of a 1 : 10,000 dilution of an eighteen to twenty-four hour culture of the test organism was now added to each tube, as well as to a control tube and a tube which contained 0.4 cc. of undiluted streptomycin solution. The final dilutions of the streptomycin gave concentrations ranging from 256 units to 0.03 unit. The tubes were incubated for eighteen to twenty-four hours and read on the basis of the presence or absence of turbidity.

If more than 2 units of streptomycin was required to inhibit growth, the bacterium was retested in a series of tubes containing gradually increasing concentrations of streptomycin in order to arrive at a closer approximation of the organism's sensitivity. This additional step was taken because of the 100 per cent error inherent in the twofold serial dilution method.

DETERMINATION OF SENSITIVITY VALUES WITHIN NARROWER RANGES THAN THOSE POSSIBLE WITH THE TWOFOLD SERIAL DILUTION METHOD

Various concentrations of streptomycin solutions were prepared in double the desired strength and added in 0.5 cc. amounts to 0.5 cc. of double strength nutrient broth which contained from 1,000 to 10,000 of the test bacteria per cubic centimeter. If the screen test of an organism showed its sensitivity to be 4 S units, it was retested with individual solutions of streptomycin containing from 1 to 8 units in steps of 1 unit of streptomycin per cubic centimeter. In like manner, organisms with screened sensitivities of 8, 16, 32 and 64 units were retested in various concentrations of streptomycin as given in table 1. Column 3 of this table gives the concentrations of streptomycin to which the organisms were exposed and the range of error which may occur in the end point. Organisms which were sensitive to 128 or 256 units in the screen test were not retested except in a few isolated instances.

RESULTS OF SENSITIVITY TESTS

The sensitivity to streptomycin of bacteria that were studied is given in table 2. These values may be compared with the serum concentrations of streptomycin in patients following the intramuscular or intravenous injection of streptomycin ranging from 25,000 to 1,000,000 S units which were reported by Buggs, Pilling, Bronstein and Hirshfeld,[2] who found that 500,000 S units of streptomycin administered intramuscularly or intravenously was sufficient to maintain a serum concentration which was at a level of 10 to 15 units at the end of four hours. Theoretically, then, all bacteria reported in this paper with a sensitivity of 8 units or less would be inhibited over a period of at least four hours by a parenteral injection of 500,000 S units of streptomycin.

Escherichia Coli.—Nineteen of 26 strains of Escherichia coli, 73 per cent, were found to be sensitive to a concentration of 8 units or less of streptomycin. Six of the strains were inhibited by concentrations of streptomycin between 12 and 32 units, while only one strain had a resistance greater than 256 units. The latter strain was isolated from the urine of a patient before streptomycin therapy was begun and may be assumed to have been naturally resistant. Four of the twenty-six strains were isolated from 1 patient and three strains from another, but in neither of these cases did the organism acquire an increased tolerance for streptomycin during therapy.

Proteus Vulgaris.—Six strains of Proteus vulgaris which were isolated from 2 patients were found to be sensitive to streptomycin, a concentration of 8 units or less being sufficient to inhibit the in vitro growth of all of them. Five of the strains were isolated during a twelve day period from an abdominal abscess of 1 of the 2 patients. Originally the organism was sensitive to 2 units of streptomycin, but after twelve days of therapy it required 8 units to inhibit its growth. In this instance Proteus vulgaris probably developed a tolerance for streptomycin. The increase in resistance, however, is not beyond the blood concentration of streptomycin that may be maintained over a period of at least four hours in a patient who has received 500,000 S units of the drug, either intramuscularly or intravenously.

Pseudomonas Aeruginosa.—The majority of the strains of Pseudomonas aeruginosa were very resistant to streptomycin, and in 2 instances it appeared that the organism developed an increased tolerance for the drug during therapy. In 1 case the resistance of the organism as recovered from bile before treatment was started was

---

[3] The streptomycin was provided through Dr. D. F. Robertson of Merck and Company, Inc., Rahway, N. J.

[4] An S unit of streptomycin, synonymous with an E. coli unit, is that amount of streptomycin which will inhibit the growth of a standard strain of E. coli in 1 cc. of nutrient broth or other suitable medium.

32 units of streptomycin. Three days later, when the organism was again isolated, its resistance had increased to more than 256 units. In the second case Pseudomonas aeruginosa was isolated from an infected ankle. It was sensitive to 20 units of streptomycin. Seven days later a reisolation of this organism was made. It now had a resistance greater than 256 units.

Of the nineteen strains of Pseudomonas aeruginosa reported in table 2, only five of them, 26 per cent, were sensitive to 8 units or less of streptomycin on primary isolation. The remaining fourteen strains required from 16 to more than 256 units for in vitro inhibition.

Aerobacter Aerogenes.—Seventeen of the twenty strains studied, 85 per cent, were sensitive to concentrations of streptomycin well within ranges that may be obtained in blood, only three of them requiring more than 6 units for the complete inhibition of growth. The one strain with a resistance greater than 256 units was the second isolation of this organism from the urine of a patient under treatment with streptomycin. When first isolated, nine days previously and two days after therapy was begun, the organism was inhibited by 1 unit of streptomycin. It would thus appear that this strain developed a decided resistance to streptomycin during its eleven days' exposure to the drug. The two strains with sensitivities of 16 and 20 units of streptomycin were primary isolations from 2 patients a few days after therapy was begun. They may have developed an increased tolerance for the drug during this period of therapy.

Staphylococci.—The vast majority of the staphylococci studied proved to be very sensitive to streptomycin, many of them being inhibited by less than 0.1 unit of the drug.

Twenty-seven strains of Staphylococcus aureus were tested. Twenty-two of these strains, or 81 per cent, were sensitive to 6 units or less of streptomycin when first isolated, and only one of the twenty-six strains presumably developed a tolerance for the drug during the course of treatment. One of the two strains requiring more than 256 units of streptomycin for inhibition was a primary isolation from a case of osteomyelitis after six days of therapy. The second of these two strains was isolated from an infected decubitus ulcer which was treated locally and parenterally with streptomycin. When first isolated this organism was sensitive to 6 units of streptomycin. On the second isolation, six days later, the sensitivity was 128 units. After three additional days of exposure to the drug the organism was able to tolerate 256 units of streptomycin.

Twenty-one of 26 strains of Staphylococcus albus, 81 per cent, were sensitive to 1 unit or less of streptomycin. In 1 instance a strain apparently developed a tolerance for the drug during thirteen days of therapy. When first isolated its sensitivity was 0.06 unit, but thirteen days later, and on two additional occasions, the resistance of the organism as isolated from the same patient was greater than 256 units. The fourth strain reported with a resistance greater than 256 units was a primary isolation following six days of therapy.

Thirteen additional strains of micrococci were tested for their sensitivity to streptomycin. These were identified as Staphylococcus epidermidis, Micrococcus candidus and Micrococcus aurantiacus. Eleven of the thirteen strains, or 85 per cent, were sensitive to 2 units or less of streptomycin.

Alpha Hemolytic Streptococci.—Thirty-seven isolations of alpha hemolytic streptococci were made from 18 patients during their course of treatment with streptomycin. Twenty-six of the strains, or 70 per cent, were sensitive to 8 units or less of streptomycin. The remaining eleven strains required 16 or more units for inhibition. In 2 instances it appeared that alpha hemolytic streptococci developed a tolerance for the drug. In a case of urinary tract infection this organism was isolated from urine on five different occasions during a period of nine days. The sensitivities were 1, 2, 4, 8 and 256 units of streptomycin. The second instance in which an alpha hemolytic streptococcus developed an increasing tolerance for streptomycin occurred with a strain isolated from a gunshot wound. Its sensitivity on primary isolation was 16 units, but twenty-seven days later when reisolated from the wound it grew very well in the presence of 256 units of streptomycin. The remaining four strains, resistant to 256 units of streptomycin, were primary isolations before therapy was begun.

Beta Hemolytic Streptococci.—Eleven of fifteen strains of beta hemolytic streptococci, or 73 per cent, were found to be sensitive to 8 units or less of streptomycin. Two strains with a sensitivity of 32 units were isolated from 1 patient before therapy was begun, and two strains that were resistant to more than 256 units were isolated from another patient twenty-one and twenty-eight days after therapy had been started. These strains may have become resistant during the course of therapy.

Diphtheroids.—The diphtheroids were found to be either extremely sensitive or very resistant to streptomycin. Thirty-six strains were isolated from 19 persons. Seventeen of these strains were sensitive to 1 unit or less of streptomycin, one required 7 units for inhibition, 6 required 256 units and 12 strains were not inhibited by 256 units of the drug. No attempt was made to identify these organisms as to species, but on two different occasions diphtheroids with a great tolerance for streptomycin were isolated from lesions which, on an earlier date, had yielded diphtheroids that were sensitive.

COMMENT

A study of the sensitivity of bacteria to antibiotics is complicated by the extreme difficulty encountered in determining with any degree of accuracy whether or not the same organism is being isolated when cultures are obtained over a period of days or weeks from a given patient. Thus, is a strain of Staphylococcus aureus isolated from a patient on one date the same organism as that isolated from the patient on a later date? At times a given organism will either disappear from an infectious process or will be present in such small numbers that it is not recovered when a culture of the infection is made. At some later date this same species will reappear. Is it the same organism that was originally present or has the patient become reinfected with another strain of the bacterium?

The problem assumes clinical importance under the following circumstances: A bacterium is isolated from a patient just before therapy with an antibiotic is begun. It is found to be very sensitive to the drug and, in view of this sensitivity, the dosage of the drug is reduced or is given at longer intervals. At a later date the same species of bacterium is reisolated and is found to be resistant to the antibiotic. May we assume that the resistant strain developed from the sensitive strain under the lower therapeutic dose or is it (1) a new invader with natural resistance or (2) a naturally resistant strain which was originally present in the lesion but for some reason was not isolated when the first culture was taken?

In the case of bacteremias it is probably safe to assume that tolerance for a given antibiotic has developed when a resistant strain is isolated subsequent to the isolation of a sensitive strain, but with open wounds this assumption may not be justified.

It often happens that two or even three colonies of Staphylococcus aureus are fished for identification and sensitivity tests from a streak plate made from an infectious process. On testing the sensitivity of these colonies, all but one of them may prove to be sensitive to the antibiotic. At a later date a second culture of the lesion is made but only one Staphylococcus aureus colony is picked. It is resistant to the drug. Is this the organism which was originally resistant or has one of the susceptible strains developed a tolerance for the drug during therapy?

There appears to be no practical solution to this problem. It seems wiser therefore to maintain as high a concentration of the antibiotic in the body fluids as is possible.

SUMMARY

Two hundred and twelve strains of bacteria, isolated from 38 patients with miscellaneous infections while under treatment with streptomycin, were tested for their susceptibility to this antibiotic. The sensitivities obtained were correlated with the blood concentrations of streptomycin known to be attained in patients under therapy.

1. The majority of the strains of Escherichia coli, Proteus vulgaris, Aerobacter aerogenes, staphylococci and streptococci were susceptible in vitro to the blood concentration of streptomycin that can be maintained in the average patient over a four hour period when given in 500,000 S unit doses. This blood concentration is known to be from 5 to 7.5 or 8 S units per cubic centimeter of blood.
2. The majority of the strains of Pseudomonas aeruginosa investigated were found to be very resistant to streptomycin.
3. Resistant strains of a given bacterium were isolated from patients subsequent to the isolation of sensitive strains. It was assumed that these resistant strains developed from the sensitive strains.
4. Diphtheroids were found to be either extremely susceptible or very resistant to streptomycin.
5. A method was adopted for determining the sensitivity of bacteria to antibiotics within narrower limits than those obtainable with the twofold serial dilution method.

PENICILLIN IN TETANUS

W. A. ALTEMEIER, M.D.
Cincinnati

Tetanus, or lockjaw, is one of the most dreaded infectious complications of wounds. Although its specific etiology has been known for sixty years and its diagnosis has been relatively easy, the treatment of tetanus, once established, is still unsatisfactory and the results are uncertain. It has been disappointing to see the failure of large doses of antitetanic serum to alter the course or lower the mortality of this disease once it has developed, particularly since a small dose of the antitetanic serum has been so effective in preventing the development of the disease when given prophylactically at the time of injury. This has been particularly true in the cases with incubation periods of less than six days. The studies of Abel and Firor [1] have revolutionized the concept of the pathogenesis of tetanus and crystallized the facts known regarding the value and limitations of active therapy of established tetanus. Firor has pointed out that the outlook in generalized tetanus is always grave and that the mortality rate is frequently determined before the patient is seen by the physician. In one group no form of therapy known at the present time will prevent a fatal outcome, while in another group, composed particularly of cases seen during the prodromal period, the issue of life or death is

determined to a large extent by the physician's ability to diagnose promptly and to treat adequately.

With these thoughts in mind, it was decided to explore the potential value of penicillin in the management of established tetanus.

MATERIAL

During the past twenty-three months we have seen and studied 16 cases of established generalized tetanus, and 14 of these were treated during a period of twelve months (table 1). Eleven patients were 10 years of age or less and the oldest patient was 32. Eleven were males and 5 were females. The primary wound was unusually small (table 1) and often so insignificant that it was overlooked until the time of admission to the hospital. In 2 instances the primary wound was unknown and was never demonstrated by clinical examinations. Five of the wounds were simple puncture wounds, 4 were infected lacerations, 3 were abrasions or deep scratches, 1 was a plastic operative wound, and the other was a recurrent ulcer of the foot. Ten of the wounds were on the lower extremity, 2 were on the face or scalp and 2 were on the hand. The incubation period of the disease was unknown in 3 cases, five or less days in 3 cases, six to ten days in 6 cases and eleven to fifteen days in the remaining 4.

TABLE 2.—*Treatment and Result*

Case	Wound Excised	Antitoxin	Penicillin	Days in Hospital	Results	Penicillin—Beneficial Results
1	No	150,000	None	17	Recovery	
2	Yes	390,000	None	9	Death	
3	Yes	340,000	280,000	60 hrs	Death	No obvious beneficial results

6	Yes	65,000	65,000	16 hrs.	Death	Did not live long enough
7	No	20,000	60,000	24 hrs.	Death	No definite beneficial results; did not live long enough
8	No	290,000	250,000	48 hrs.	Death	None apparent
9	No	50,000	960,000	17	Recovery	Mild case; no obvious benefit
10	Yes	150,000	1,445,000	25	Recovery	No beneficial effects apparent
11	No	250,000	1,255,000	23	Recovery	Definite benefit; control of pneumonia and lowering of temperature
12	No	60,000	225,000	60 hrs.	Death	None
13	No	20,000	145,000	30 hrs.	Death	None apparent
14	Yes	100,000	605,000	4	Death	None apparent
15	Yes	260,000	500,000	4	Death	None apparent
16	Yes	140,000	700,000	5	Death	None apparent

METHODS

All of the patients received antitetanic serum intravenously or intramuscularly as soon after diagnosis as possible (table 2). The amount of antitoxin administered varied between 20,000 and 390,000 units. Fourteen of the patients received 50,000 or more units, 10 received 100,000 units or more and 5 received 250,000 or more units. In 9 instances the primary wound was excised one hour after infiltration of 10,000 to 20,000 units of antitetanic serum into the surrounding area. The resultant wound was left open and treated topically by the daily application of zinc peroxide-calcium peroxide ointment.[2] Penicillin was administered to 13 of the patients, and the remaining 3, not receiving it, were used for contrast. The usual dose was 15,000 units every three hours. In 8 cases a total of 500,000 or more units of penicillin was given, and 3 patients received a total of 1,000,000 to 1,500,000 units. All of the patients would have received a million or more units of penicillin if they had lived long enough.

RESULTS

There were 10 deaths and 6 recoveries, giving a mortality rate of 62.5 per cent. Nine of the 13 patients treated with penicillin died. An analysis of these deaths is interesting. All of the patients with incubation periods known to be five days or less died, 4 of 6 patients with incubation periods of six to ten days died, only 1 of 4 with incubation periods of eleven to fifteen days died. Two of the 3 with unknown incubation periods died. The clinical courses of these 2 patients with death occurring thirty and sixty hours after admission to the hospital strongly suggested that their incubation periods were also less than five or six days. These observations reemphasize the relationship of high mortality rate and short incubation period.

TABLE 3.—*Causes of Death*

Case	Cause of Death
2	Gas gangrene on eighth day; died two hours after amputation
3	Respiratory arrest during convulsion
6	Died sixteen hours after admission in convulsion with respiratory arrest
7	Toxemia; pyrexia
8	Respiratory arrest
12	Toxemia; respiratory arrest
13	Toxemia; respiratory arrest; pyrexia
14	Respiratory arrest; toxemia; pulmonary edema
15	Respiratory arrest
16	Respiratory arrest; toxemia

The amount of antitoxin given did not seem to affect the rate of survival. Four of the 5 patients receiving 250,000 or more units of tetanus antitoxin died, 5 of the 10 patients receiving 150,000 units or less died and 4 of the 6 receiving 75,000 units or less died. No immediate reactions to the serum occurred, but typical serum sickness developed in case 10.

Experience has shown that clinical improvement in most established infections usually occurs within eighteen to seventy-two hours after the onset of treatment with penicillin. In contrasting the cases in which penicillin was administered with those in which it was not, no obvious beneficial effects such as a fall in the temperature and pulse rates, or definite decrease in the incidence, duration or severity of convulsive seizures were noted in the course of the disease that could be attributed to the administration of penicillin, except in case 11. This child had developed a complicating pneumonia during the prolonged anesthesia produced by solution of tribromoethanol, and the administration of penicillin was followed within thirty-six hours by definite clinical improvement with a fall in the temperature and pulse rates, although the signs of tetanus continued to run their course. It is interesting to note that 6 of the 9 deaths of patients receiving penicillin occurred within sixty hours or less after admission to the hospital and the start of therapy. Respiratory arrest was the immediate cause of death in 8 of these 9 cases (table 3). Associated conditions at death were pulmonary edema, hyperpyrexia and evidence of profound toxemia. None of the patients with incubation periods of five days or less survived.

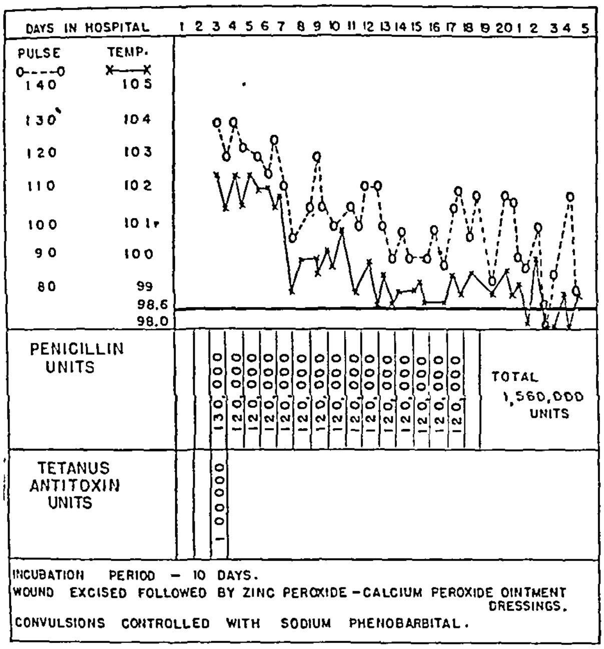

Chart 1.—Clinical course of patient 4, treated with antitoxin and penicillin

The results of treatment which are of especial interest are illustrated in the following 5 representative cases:

Case 4.—L. H., a white boy aged 7 years, admitted to the hospital on July 13, 1944, had received a small puncture wound on the dorsum of his left foot ten days before admission while running through a field of wheat stubbles. A local infection developed, which the mother treated with poultices of onions each night. The appearance of the local lesion improved, but three days before admission he began to complain of pain in the back. The day before admission, while playing, he fell twice and seemed to be very awkward. On the day of admission he complained of increasing pain in the back, inability to open the jaw, and stiffness of the neck and back.

On examination the boy appeared well developed, well nourished and dirty, and he was extremely alert and apprehensive. It was impossible to open his mouth more than 1 cm. A small infected puncture wound about the size of a quarter (24 mm.) was present on the dorsum of the left foot just proximal to the third and fourth toes. The musculature of the abdomen, back and extremities was rigid and in tonic spasm. All reflexes were hyperactive, and there was sustained clonus of the left ankle.

He received 90,000 units of tetanus antitoxin by the intramuscular and intravenous routes, and an additional dose of 10,000 units was injected about the wound. One hour later the wound was excised and a splinter of wood was found in its center. Culture of the wound showed Clostridium tetani. The resultant area was packed open with gauze saturated in zinc peroxide-calcium peroxide ointment. Penicillin therapy was also used, 15,000 units every three hours for a total dose of 1,560,000 units. Under this treatment his condition at first became worse. The neck rigidity, trismus and back rigidity increased and clonic spasms developed. These were controlled fairly well by frequent injections of phenobarbital sodium. After three days, however, these signs gradually decreased, and he began to recover (chart 1). The wound assumed a healthy appearance and healed by secondary intention. When the patient was dismissed from the hospital twenty days later, the skeletal muscles of the extremities, back and abdomen were still moderately spastic, although he was able to open his mouth widely. Subsequently his family physician reported that he had made a complete recovery.

This was a moderately severe case of tetanus with an incubation period of ten days resulting from an infected puncture wound of the dorsum of the left foot. Although the patient recovered, it was impossible to attribute any beneficial results to penicillin.

Another case of tetanus with an incubation period of eleven days, treated with tetanus antitoxin but without penicillin, was used for contrast with the preceding one:

Case 5.—R. N., a white boy aged 10 years, was admitted to the Cincinnati General Hospital with a history of having fallen three weeks before on a piece of broken glass, cutting his knee. The wound bled freely and was washed with warm water and covered with a clean cloth. About four hours later the family physician washed it with a disinfectant and approximated the wound edges with adhesive tape. The child bumped the knee severely enough to open it again three times during the next few weeks. A little more than a week before admission the patient developed stiffness of the thigh, neck and back muscles and rigidity of the jaws. Two days before admission he developed clonic convulsions with no loss of consciousness.

The patient was well developed and well nourished. There were risus sardonicus and rigidity of the jaws. A laceration on the right knee showed induration of the surrounding tissues but no lymphadenitis nor lymphangitis. The deep reflexes of the lower extremities were somewhat hyperactive, and ankle clonus was sustained bilaterally.

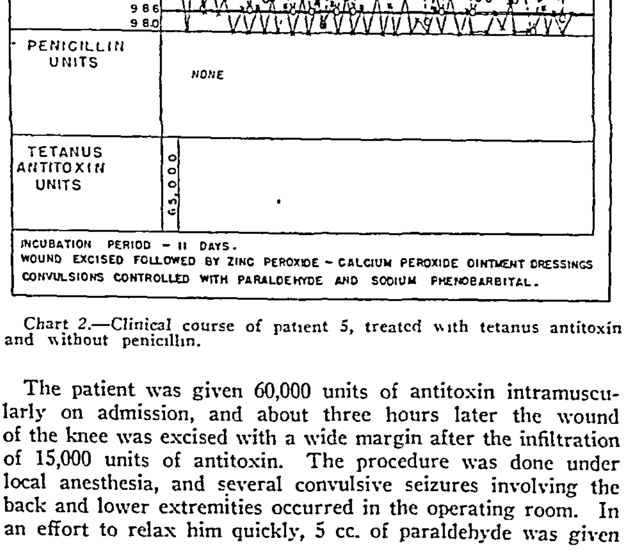

Chart 2.—Clinical course of patient 5, treated with tetanus antitoxin and without penicillin.

The patient was given 60,000 units of antitoxin intramuscularly on admission, and about three hours later the wound of the knee was excised with a wide margin after the infiltration of 15,000 units of antitoxin. The procedure was done under local anesthesia, and several convulsive seizures involving the back and lower extremities occurred in the operating room. In an effort to relax him quickly, 5 cc. of paraldehyde was given intramuscularly, but the stimulation of the pain caused by this sent him into a series of generalized tetanic spasms He was kept mildly sedated with paraldehyde and phenobarbital For three days the patient's condition did not improve but seemed to get worse Beginning with the fourth day after admission, definite signs of improvement became obvious with a fall in temperature and a decrease in the number and severity of convulsive seizures (chart 2) The local wound was treated with zinc peroxide-calcium peroxide ointment applied every forty-eight hours On the twenty-first day it was grafted with skin successfully The patient was discharged on the thirty-first hospital day much improved but still somewhat spastic

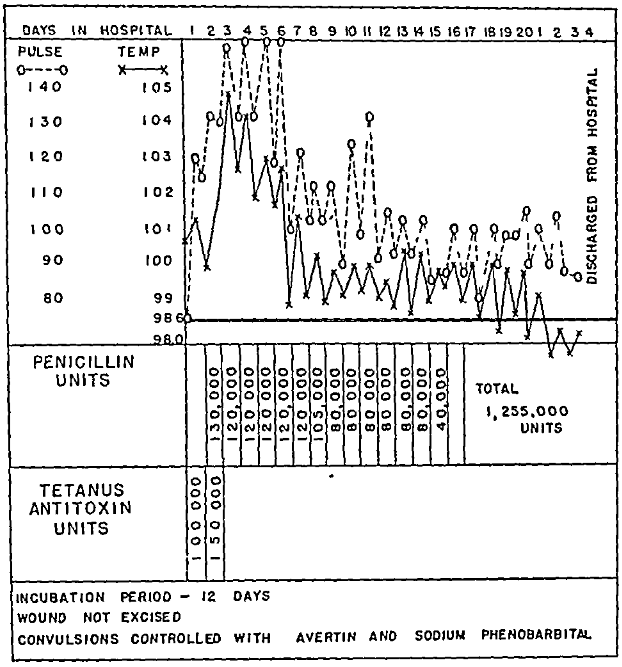

Chart 3 —Definite improvement in clinical course of patient 11 attributable to effect of penicillin on pneumonia complicating the tetanus

Although case 5 treated without penicillin was probably somewhat less severe than case 4 treated with penicillin, it is obvious that in neither was a fatal dose of tetanus toxin fixed in the central nervous system The response of the temperature and pulse to therapy was no better in the case in which penicillin was employed, and the other signs of tetanus subsided at about the same rate in the 2 patients

Case 11 —M R, a white girl aged 8 years, was admitted to the hospital on Jan 20, 1945 with a history of inability to open her mouth for two days Two weeks before admission she had struck a tree stump while sled riding and scratched her chin and neck The wounds appeared to be superficial scratches and apparently healed normally without medication or consultation with a physician She had never received passive or active tetanus immunization Three days before admission the child became irritable and forty-eight hours later she developed inability to open her mouth, headaches and restlessnesss Four hours before her entrance into the hospital she had several generalized convulsions associated with pain and stiffness of the back

Examination showed obvious risus sardonicus and opisthotonos Her temperature was 100 6 F and pulse rate 110 The teeth were tightly clenched, and any attempt to open the mouth passively or actively produced pain There were several superficial healed scratches on the face that showed no evidence of infection The abdominal muscles were in tonic spasm and the abdominal reflexes were hyperactive There was resistance to passive movement of the extremities, and all deep reflexes were hyperactive

The patient was given 100,000 units of tetanus antitoxin intravenously soon after her admission and 150,000 units during the second twenty-four hour period Phenobarbital sodium failed to control the patient's convulsive seizures, which occurred every five to fifteen minutes, and it became necessary to administer solution of tribromoethanol Occasionally convulsive seizures became severe and caused the patient to groan, even though she was anesthetized with the tribromoethanol Phenobarbital sodium was administered as necessary in addition to the tribromoethanol when the convulsions became very severe

An airway was placed in the mouth and the excessive mucous secretions were aspirated by suction as necessary The convulsions continued throughout the third day after admission, and physical signs of bilateral bronchopneumonia developed The temperature rose to 105 F, the face became flushed, and the skin was pale and hot Convulsive seizures occurred at intervals of ten minutes and the respirations became deep and labored at 4 p m on this day Penicillin was started at this time, 10,000 and then 15,000 units intramuscularly every three hours Tribromoethanol therapy was continued

The temperature began to fall thirty-six hours later, reaching 99 F on the fourth day after the onset of penicillin therapy (chart 3) Thereafter the child continued to improve and several days later was able to open her mouth sufficiently to drink and enjoy water and milk The convulsive seizures disappeared and the tonic spasms of the skeletal musculature gradually decreased The dose of penicillin was decreased to 10,000 units every three hours and it was discontinued on February 3 She received a total of 1,255,000 units of penicillin administered over a period of fourteen days The patient was discharged from the hospital on February 10 and was able to walk out of the hospital, although she was still somewhat spastic

In this case recovery was unquestionably due to the combined use of antitoxin, penicillin and adequate sedation Although definite clinical improvement followed the start of penicillin therapy, we believe this improvement resulted largely if not entirely from the control of the bronchopneumonia which had developed, and not from any effect on the tetanus directly

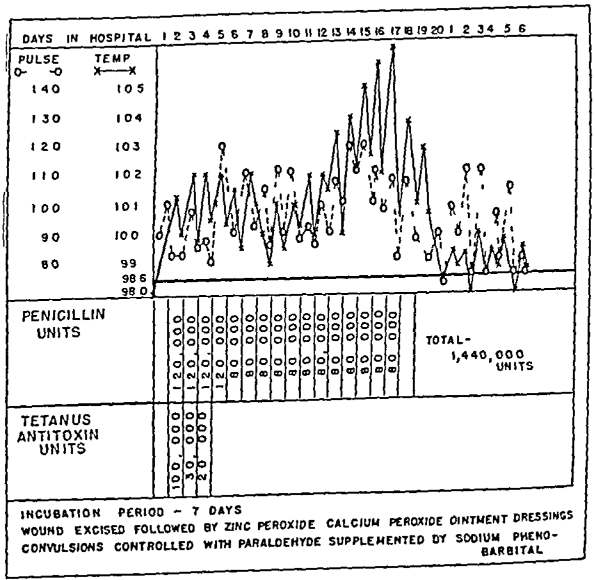

Chart 4 —Clinical course of case 10 treated with penicillin and tetanus antitoxin Serum sickness on eleventh day as result of serotherapy No apparent benefit from penicillin

Case 10 —R K, a white man aged 25, was admitted to the hospital on Jan 6, 1945 with a history of having received superficial lacerations of both legs on the front step of a farm house about Dec 27, 1944 On January 3 stiffness of the jaw occurred, and this increased daily On the 6th anorexia, inability to open the mouth, stiffness of the neck, dysphasia and vague anterior chest pains developed.

On physical examination his temperature was 98.4 F., pulse rate 90 and respiratory rate 30. He appeared clear mentally, and his position was one of typical opisthotonos. Risus sardonicus and trismus were present, and any effort to open the mouth resulted in pain. The pupils reacted poorly to light, the right reacting better than the left. The abdominal muscles were spastic. There was moderate resistance to passive movement of the upper extremities, and the muscles of the lower extremities were held in tonic spasm. All reflexes were hyperactive, and there was sustained left patellar and ankle clonus.

The patient received 40,000 units of tetanus antitoxin intravenously and 40,000 units intramuscularly soon after admission. An additional 20,000 units of tetanus antitoxin was injected about the lesions. One hour later the wounds were excised and packed open with dressings of zinc peroxide-calcium peroxide ointment, which were changed daily thereafter. In the following four days he received 70,000 units of tetanus antitoxin. In addition, immediately after admission, he received 120,000 units of penicillin daily given intramuscularly in doses of 15,000 units every three hours for four days and 10,000 units for another ten days. The total amount of penicillin administered was 1,445,000 units. Effective sedation was obtained with paraldehyde supplemented by phenobarbital sodium. His condition remained more or less stationary for four days, and then the muscle spasticity and convulsive seizures lessened. The temperature and pulse rates remained elevated, however (chart 4). On the eleventh day after admission he developed signs of serum sickness, which became accentuated and gradually subsided during the following nine days. Thereafter his improvement was uninterrupted.

Case 16.—W. B., a white youth aged 16, was admitted to the hospital on June 10, 1945 with a history of having scratched his leg one week before on a bicycle pedal. He received no local treatment nor prophylactic injection of tetanus antitoxin. On the day before admission he began to have difficulty in swallowing and opening his mouth. This increased rapidly and was accompanied by stiffness and pain in his neck. There was no history of convulsions up until the time of admission.

Physical examination showed that the patient was well developed and well nourished. His temperature was 100.1 F., pulse rate 110 and respiratory rate 22. Spasm of the masseter muscles, rigidity of the jaws, risus sardonicus, rigidity of the neck, back and abdomen, and hyperactive reflexes were present. A small superficial abrasion without cellulitis or tenderness was present on the lateral aspect of the right leg. The white blood cell count was 7,000, the red blood cell count 4,900,000 and the hemoglobin 12.75 Gm. Urinalysis was essentially negative. A diagnosis of tetanus was made and immediate treatment was started.

After a negative skin test, a dose of 20,000 units of tetanus antitoxin was injected about the wound. An additional 40,000 units of tetanus antitoxin was given intramuscularly and another 40,000 units given intravenously. Phenobarbital sodium 3 grains (0.2 Gm.) was given hypodermically. One hour later the wound on the right leg was excised under local anesthesia after preliminary cleansing with soap and water. The subcutaneous tissues were found to be discolored and hemorrhagic down to the underlying fascia. The wound was excised and the wound was packed open with gauze impregnated with zinc peroxide-calcium peroxide ointment. Penicillin in doses of 20,000 units was given immediately after admission and every three hours thereafter.

At 2 a. m. June 11 the patient began to have sharp shooting pains in his back every ten minutes. Codeine in 1 grain (0.06 Gm.) doses gave temporary relief. The patient became quite restless and had more extensive and more frequent pains associated with convulsions. The duration of the pains increased and the intervals between attacks decreased until they were almost continuous. He was given 8 cc. of paraldehyde in 2 ounces (60 cc.) of olive oil by rectum and this relaxed him sufficiently to permit sleep. This was repeated every three hours during the following day. At 2 o'clock in the morning of the 12th the patient began to have frequent convulsions, and the dose of paraldehyde by rectum was increased to 12 cc. every three hours. This quieted him considerably, although he continued to have occasional convulsions. Parenteral fluids for general support were given by continuous intravenous injection.

At 6 a. m. on the 12th the patient began to have very severe convulsions which resulted in complete respiratory arrest for several minutes. Artificial respiration was given successfully, and the administration of paraldehyde was continued. Pentothal sodium 5 cc. was started intravenously with the next severe convulsion. It was very effective temporarily and relaxed the tonic spasm of the skeletal muscles considerably. However, severe convulsions again occurred and were followed by periods of complete respiratory arrest. During the attacks of respiratory arrest the patient became pale, then mottled, and finally extremely dark and cyanotic. After the administration of artificial respiration and the injection of pentothal sodium intravenously, regular respirations were resumed. Intocostrin in doses of 3 cc. was given every two hours and nasal oxygen therapy was started.

On June 13 the patient developed acute pulmonary edema, which was controlled by the usual methods. He continued to have attacks of respiratory arrest, and these were overcome with more and more difficulty on this day. In all, he had nine attacks of complete arrest of respiration. Intocostrin was discontinued on the 13th and during the day of the 14th the patient's general condition seemed much improved. He had no convulsions for twenty-four hours and was resting comfortably. The neck and back were still in the position of opisthotonos. In the evening of the 14th the patient commenced to have extremely painful convulsions, which continued throughout the early morning hours of the 15th. He remained perfectly rational in spite of the doses of paraldehyde and pentothal sodium.

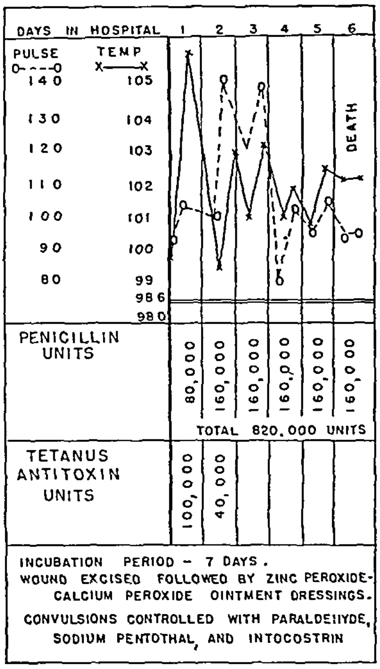

Chart 5.—Course of patient 16, treated with penicillin and tetanus antitoxin.

At 6:45 a. m. on the morning of the 16th he developed a severe convulsion and ceased breathing during it. At 6:55 his pulse became imperceptible, and artificial respiration, cardiac massage and an injection of intracardiac epinephrine failed to revive him.

COMMENT

Reports[3] of cases of tetanus in which recovery occurred after treatment with both antitetanic serum and penicillin have led to an impression that penicillin is a life saving measure in this disease. Our studies have not substantiated this impression.

Tetanus is essentially an infectious disease developing after a variable incubation period and caused by a potent water soluble toxin produced in a wound infected by Clostridium tetani. The responsible wound in civilian practice is usually small and often insignificant (table 1). The chief reason for this is probably that patients with large wounds almost routinely receive one or more prophylactic injections of tetanus antitoxin, whereas those with small wounds do not, usually because of their failure to go to their physician for one treatment. In tetanus it is not the presence of local tissue destruction or signs of invasiveness usually associated with other infections of wounds which present any difficulty in management. Instead it is the production, distribution and fixation in susceptible tissues of extremely small quantities of the specific and powerful toxin. I have seen fatal and typical cases of tetanus originating from primary wounds containing but one drop of pus. In other instances the wound was so insignificant that it completely escaped notice. After a fatal dose of the toxin has become fixed in the central nervous system, death apparently is inevitable under the present methods of treatment. The failure of antitetanic serum, even in extremely large doses, is well known in established clinical and experimentally produced tetanus when a fatal dose of toxin has been fixed in the central nervous system. This is in sharp contrast to its effectiveness in the prevention of tetanus when a prophylactic dose of 1,500 units is administered at the time of injury.

---

[3] Buxton, R., and Kurman, R. L.: Tetanus: A Report of 2 Cases Treated with Penicillin, J. A. M. A. **127**: 26 (Jan 6) 1945.

Although penicillin exerts a definite bacteriostatic effect on Cl. tetani, it has no known effect on its toxin. Preliminary experiments here in mice have failed to show any inhibition of the action of tetanus toxin by penicillin. Therefore it is no surprise that our studies have failed to demonstrate any beneficial effect of penicillin on the course of established clinical tetanus.

When complications such as pneumonia or secondary invasive wound infections occur during the course of tetanus, the administration of penicillin is of definite value in their control, as illustrated in case 11.

The failure of penicillin to alter appreciably the course of established tetanus reemphasizes several very important concepts: (1) that the length of the incubation period is the most important single prognostic sign, (2) that the essential primary cause of the disease is a bacterial toxin and (3) that successful management depends not on chemotherapy but on early diagnosis during the prodromal period, immediate neutralization by specific serotherapy of all existing free toxin in the body, removal of the source of toxin, control of the convulsive seizures, control of the attacks of respiratory arrest and the administration of general supportive measures.

SUMMARY

A clinical study of 16 cases of established generalized tetanus has failed to show evidence of any beneficial effect of penicillin on the course of this disease. There was no obvious fall in the temperature or pulse rates as has been repeatedly seen in other infections susceptible to its action, no decrease in mortality or morbidity nor any definite decrease in the severity, duration and frequency of the convulsive seizures which could be attributed to the action of penicillin. Exceptions may be found in cases of tetanus complicated by pneumonia or other infections susceptible to penicillin. In such instances, however, the improvement that occurs is due to the effect of the chemotherapeutic agent on the complicating infection and not on tetanus.

The evidence indicates that until some direct attack is possible on the fixed toxin or the products of its fixation in the central nervous system, the successful management of tetanus depends not on chemotherapy but on early diagnosis, adequate serotherapy for neutralization of free toxin, control of the convulsions and the administration of general supportive measures.

OCCURRENCE OF BRUCELLA MELITENSIS IN IOWA

CARL F. JORDAN, M.D., M.P.H.
Des Moines, Iowa
and
IRVING H. BORTS, M.D.
Iowa City

Brucella melitensis, the species of Brucella with usual source in goat and sheep, is now known to occur endemically in Iowa. Brucella abortus and Brucella suis, etiologic agents for brucellosis in cattle and hogs respectively, have been recognized and observed in Iowa since 1927. On the other hand, brucellosis of man caused by Brucella melitensis was for years considered an exotic type of disease in this area. The present report, based on laboratory findings and epidemiologic investigations, presents data referable to 20 cases of brucellosis diagnosed in Iowa during the past two years and found to be caused by the caprine strain of brucella, Br. melitensis.

ISOLATION OF BRUCELLA IN IOWA

During the period July 1, 1927 to June 21, 1945 brucella strains totaling 339 were recovered from human sources in the State Hygienic Laboratory by or under the direct supervision of one of us (I. H. B.). Of these strains 228 (67.3 per cent) were Br. suis, 83 (24.5 per cent) Br. abortus and 26 (7.7 per cent) Br. melitensis. Two (0.5 per cent) remain untyped because of dissociation.

BRUCELLA MELITENSIS STRAINS IN IOWA

Of the twenty-six strains of Brucella melitensis thus far isolated, all but one have come to light since December 1943. The solitary strain of Br. melitensis isolated in Iowa during June 1930 was recovered from the blood of a Mexican, a railroad employee then hospitalized in this state, who apparently acquired infection in Mexico previous to arrival in this country.[1]

Br. melitensis was isolated from the blood of 2 packing house workers in Iowa during December 1943. These mark the first 2 instances of brucellosis acquired in this state in which the melitensis species of Brucella was discovered to be the causative organism. In 1944 additional melitensis strains numbering fourteen were cultured from the blood of farmers and packing house employees. From Jan. 1 to June 21, 1945 isolations of this type numbered nine, making a total of twenty-six at the time of this report.

BLOOD CULTURE AND BLOOD CLOT CULTURE

In the series of twenty-six melitensis cultures here reported, eleven brucella strains were isolated from blood cultures (tryptose broth medium, p_H 6.8) as secured and forwarded to the State Hygienic Laboratory by attending physicians. The remaining fifteen strains were isolated from the blood clots of specimens submitted by attending physicians for agglutination tests. At present only the clots of specimens showing brucella agglutinins in the serum are cultured for the specific organism.

Dr. Jordan is director, Division of Preventable Diseases, and Epi- [illegible] Iowa State Department of Health, Des Moines [illegible] State Hygienic Laboratory, Iowa State Depart- [illegible] assistant professor of hygiene and preventive [illegible] of Iowa College of Medicine.

[1] Jordan, [illegible] and Borts, I. H.: Double Infection by Organisms of the Brucella Group, Pub. Health Rep. 46: 2437-2443 (Oct. 9) 1931.

When obtained, growth is identified on the basis of its gram stain, agglutinability with known antibrucella serum, hydrogen sulfide production and the bacteriostatic action of dyes as recommended by Huddleson.[2]

BLOOD CULTURES

Significance and Procedure.—The blood culture is of first importance among methods of confirming clinical diagnosis. Moreover, the isolation of Brucella with subsequent species identification is the only means of tracing infection to the proper source in domestic animals. Next in importance to the blood culture as a laboratory aid to the physician is the agglutination test. The skin test and opsonocytophagic test are indicative of exposure to infection in the recent or remote past but must be interpreted with great caution.

Organisms of the Brucella group grow best in tryptose broth.[2] The blood culture bottle containing 100 cc. of broth is inoculated with 3 to 5 cc. of blood. The blood should be taken during the afternoon or at the height of fever; strict asepsis must be observed, preferably with use of autoclaved needles and syringes. The blood culture should be incubated for several days, when possible, before forwarding to the diagnostic laboratory. Following arrival at the laboratory, blood cultures are subcultured biweekly to solid, tryptose agar medium, with prolonged incubation in an atmosphere containing 10 per cent carbon dioxide. This procedure is carried out for twenty-one days before a blood culture is discarded as negative.

Procedure with Blood Clot Culture.—In the absence of a blood culture, the bacteriologist in the quest for Brucella turns attention to the blood clot of the specimen submitted for the agglutination test. This procedure is often unsatisfactory in that spore forming and other bacteria are commonly present in the specimen on arrival at the laboratory. Such contaminations are the result of failure to use autoclaved syringes and needles or proper care in transferring the specimen from the syringe to the sterile test tube.

Beginning in July 1944, effort was made to find a suitable culture medium which would dissolve the blood clot and provide necessary nutriment for Brucella cultivation. The mediums devised by Sellers and Morris[3] and by Bohls and Schuhardt[4] were subjected to further modification. The elimination of glycerin and the substitution of as little as 0.2 per cent of tryptose for peptone in these formulas were found to enhance the growth of Brucella, with no additional benefit gained in concentrations beyond 2 per cent. The addition of para-aminobenzoic acid resulted in maintenance of growth for many months.

Blood clots of specimens are handled in the following manner: After centrifugation, the serum is drawn off with a capillary pipet under rigid asepsis. The clot is poured carefully into a tube of tryptose-bile medium. Clot cultures are incubated under 10 per cent carbon dioxide and are subcultured to tryptose slants weekly for three weeks before being discarded as negative.

LABORATORY DATA

Information regarding agglutination reactions and blood and clot culture isolations in the series of 20 melitensis cases thus far studied is contained in table 1.

CLINICAL MANIFESTATIONS

Illness due to Br. melitensis infection was characterized by fever, chills or chilliness, sweating, weakness; loss of weight, headache, muscular pains and leg pains. Although the course was mild in several cases, infection was generally more severe than that caused by Br. abortus and comparable with illness due to Br. suis. Rash, nosebleed, glandular swellings and nasal ulceration were noted in several of these cases. The rash, macular in character, resembles that seen in streptococcic septicemia; glandular swellings may simulate those of Hodgkin's disease.

EPIDEMIOLOGIC DATA

It is desired to emphasize the primary importance of the laboratory findings in this series of cases. Epidemiologic investigations were prompted by and dependent on isolation and identification of Br. melitensis in the laboratory.

Detailed information with reference to 20 of the 26 patients from whose blood Br. melitensis was isolated was secured from case reports completed through courtesy of Iowa physicians and through field investigation in cooperation with attending physicians and veterinarians.

Table 1.—*Brucella Melitensis Infection in Iowa*

18	M. D.	45	1:640	3/13/45	....	4/ 5/45
19	A. R.	40	1:1,280	5/ 9/45	....	6/25/45
20	C. P.	27	1:1,280	5/26/45	....	5/26/45

Age and Sex Distribution (shown in table 1).—All of the patients were males; the youngest was 8 years of age, the oldest 51. Ten of the 20 were in the age group 30-39, and all but 3 were in the age groups 20-59.

Residence; Occupation.—The patients reside in ten different counties with distribution in central, north central and northeastern Iowa, but including areas as widely separated as southwestern Iowa and the eastern border of the state.

Of the 20 patients 10 were packing house employees; the remaining 10 were farm workers, farm residents or visitors (table 2).

Use of Dairy Products.—Raw milk was used by the patients on farms, while the packing house employees, with one or two exceptions, drank pasteurized milk prior to onset of symptoms.

Contact with Livestock.—Table 2 indicates types of contact with livestock. All of the patients gave the history of direct contact with domestic animals, with one exception. This patient (18, M. D.), a painter, worked on several farms during the months prior to illness. On one farm he painted a hog house. Hogs are said to have "nosed at the staging." By rubbing or otherwise, these animals may have contaminated ladders or planks conveying infection to the patient indirectly.

It is noteworthy (table 2) that only 7 of the 20 patients concerned gave a history of direct contact with sheep. Two of these patients stated that such contact occurred some years prior to the recent illness. One (9, H. A.) had judged sheep at county fairs in Iowa ten years preceding his illness. The other patient (16, A. G.) had worked with sheep on ranches in Montana during 1935-1937. Whether the history of contact with sheep in the remote past is significant in these cases is problematic and cannot be affirmed. That infection in these 2 instances may be traceable to hogs is suggested by the fact that on both farms (cases 9 and 16, table 2) sows had lost pigs during months preceding human illness. Of the 7 patients who had contact with sheep, 5 had also been in direct contact with hogs, and 3 with cows.

highly probable that further study will reveal that hogs, in addition to serving as the usual reservoir for Br. suis, will also prove to harbor Br. melitensis.

Evidence to show that hogs are susceptible to Br. melitensis has been presented by Huddleson,[5] who states: "Melitensis is pathogenic for the hog. While I was in Malta in 1938 I saw evidence of its pathogenicity. A considerable amount of left-over unpasteurized goat's milk was fed to a group of pregnant sows. All of them aborted. Melitensis was recovered from the fetuses. For some reason this observation was never reported in the literature."

McNutt[6] has reported isolation of Brucella from the organs and tissues of hogs at the time of slaughter. He[7] states that all strains which were isolated from hogs in 1938 were of the porcine type of Brucella, Br. suis.

According to Castenada, Tovar and Velez,[8] Br. melitensis represents the most common type of brucellosis in Mexico. Of 158 strains isolated by these workers, 143 were Br. melitensis, 5 Br. abortus and 2 Br. suis.

History and Evidence of Brucellosis in Animals.—Table 2 presents additional information regarding brucellosis in animals suspected as the probable source of infection. In the group of 10 packing house employees, history of infection in animals is undetermined. Of the 10 instances in which infection was acquired on farms, there was no history of abortion in sheep. On the other hand, on five of these farms, sows had lost pigs and, on a sixth farm, 8 or 9 sows were found to react positively to the agglutination test for brucellosis.

COMMENT

The isolation of Br. melitensis from the blood of persons in Iowa who during the past two years have suffered an attack of brucellosis demonstrates that infection due to this species of Brucella must now be considered endemic in Iowa.

Sheep and goats are regarded as the usual animal reservoirs of infection caused by Br. melitensis. In the series of cases presented in this report, there is no history of contact with goats. Moreover, while 7 of the 20 patients in this series gave the history of direct contact with sheep in the recent or remote past, 12 had direct contact with hogs only and no known contact with sheep. On the basis of epidemiologic findings it is

It is probable that Br. melitensis has been introduced into Iowa during the past decade and that this species of Brucella has been transmitted to hogs from sheep imported originally from western and southwestern sections of this country.

SUMMARY

Brucella melitensis infection is now known to be endemic in Iowa. This organism was isolated from the blood of 20 patients. Isolation of Brucella from the blood culture of patients and from the clot of blood specimens submitted for the agglutination test was of primary importance. Identification of strains as Br. melitensis served as the basis for subsequent field study.

All of the patients were males. Ten were farm residents and 10 packing house employees.

Epidemiologic study of Br. melitensis infection in Iowa incriminates hogs as a probable and major source of infection.

Further study is planned, in cooperation with the Bureau of Animal Industry, the State Department of Agriculture and veterinarians, with the purpose of isolating Br. melitensis from the tissues of hogs or other animals incriminated as sources of infection.

BACKACHE

HENRY W. MEYERDING, M.D.
and
FORREST L. FLASHMAN, M.D.
Fellow in Orthopedic Surgery, Mayo Foundation
Rochester, Minn.

Separation of the neural arch, a condition which has been described in early papers dealing with vertebral anomalies and spondylolisthesis, has long been recognized, and the importance of this defect of the isthmic zone has been pointed out as the basis for the condition spondylolisthesis. It is also known as prespondylolisthesis, spondylolysis, rachischisis and spondyloschisis. It is probably not too well known that defects of the isthmic zone are frequently encountered, that they can be present without producing symptoms of spondylolisthesis and that they can cause disabling low back pain, especially when the back is subjected to unusual strain. The first case of a combination of spondylolisthesis and protrusion of an intervertebral disk was reported in 1939 by Baker, Love, Cameron and one of us.[1] The frequency of occurrence of separation of the neural arch was pointed out in 1924 and in 1931 by Willis,[2] who found an incidence of 4.28 per cent in 748 skeletons, 3.8 per cent occurring at the last lumbar vertebra. It is our impression that this defect is often present but is unrecognized unless oblique roentgenograms are studied, since routine anteroposterior and lateral views of the spinal column may fail to show it.[3]

The term "isthmic zone" is used to designate the pars interarticularis or isthmus, or that portion of a vertebra between the superior and inferior articular processes. This area is a narrowed bridge of bone and furnishes the only true bony support of the vertebral column. Defects of this bony bridge, or isthmic zone, may be congenital or traumatic, probably both, and it is very likely that defects in bony continuity held together by fibrous or cartilaginous tissue may be ruptured by trauma and precipitate backache, although many patients give a history of long duration and gradual onset.

Chandler,[4] in an attempt to determine whether or not there was any direct connection between developmental defects of the isthmic zone and those which were found clinically or post mortem, made a microscopic study of a series of fetal spinal columns but was unable to show a single instance of divided osteogenetic center of the lamina. Osteogenesis was found to begin in the isthmic portion and to extend gradually in both directions, anteriorly to the pedicle and superior articulation, and posteriorly to the lamina and inferior articulation. He said that "in several instances it was noticed that ossification progressed by forming cystlike spaces, the thin shell of bone replacing the cartilage in the region of the isthmus." He suggested that this might leave a vulnerable spot in the isthmus, which then might give way under certain conditions of stress.

One of us[5] has suggested that an injury at or shortly after birth may produce a bone infarct with resultant softening and later a picture strongly suggestive of osteochondritis. Also he believes that trauma is the exciting factor but that underlying it in most instances is a defect and that injury may be considered the principal etiologic factor and a congenital lesion the anatomic or predisposing factor.

Chandler has expressed the belief that the incomplete fissure occasionally seen in the roentgenogram at the region of the isthmus adds weight to the hypothesis of defective ossification rather than fracture. He stated that "complete division through the isthmus with separation of the fragments must be attributed to trauma, either acute or chronic."

Clinically there may or may not be a history of trauma. Many patients complain of backache of many years' duration, and the majority of them have had the usual conservative treatment by a number of physicians. They frequently complain of low back pain, with extension across the small part of the back but rarely of pain in the legs. The pain is aggravated in direct proportion to the amount of strain placed on the back, and therefore the complaint of an unusual amount of backache following sitting or standing in one position for a very long time is suggestive of instability resulting from a defect of the isthmic zone. The patients may receive varying degrees of relief of symptoms by decreasing activities, by wearing a firm support to the back or from lying down and resting. The physical examination may reveal that the patient has an essentially normal back, or it may reveal varying degrees of muscle spasm, tenderness and limitation of motion. In some cases there may be extension of pain down one or both legs, and herniation of a disk has been associated with the defect.

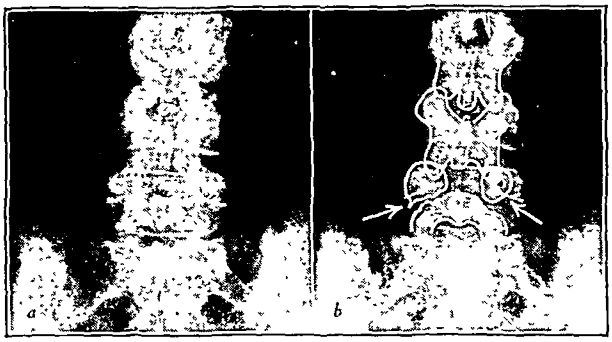

Fig. 1.—*a*, anteroposterior view demonstrating bilateral defects in the isthmic zone of the fifth lumbar vertebra; *b*, defects outlined.

The diagnosis depends usually on a careful history and an examination for the defect in those patients whose story suggests instability of the spinal column. At the time of roentgenographic examination of patients

[5] Meyerding, H. W.: Spondylolisthesis, Surg., Gynec. & Obst. 54: 371-377 (Feb.) 1932; Spondylolisthesis as an Etiologic Factor in Backache, J. A. M. A. 111: 1971-1976 (Nov. 26) 1938; Low Backache and Sciatic Pain Associated with Spondylolisthesis and Protruded Intervertebral Disk: Incidence, Significance and Treatment, J. Bone & Joint Surg. 23: 461-470 (April) 1941; Spondylolisthesis: Surgical Treatment and Results, ibid. 25: 65-77 (Jan.) 1943.

who have other conditions of the lower part of the back the defect is also found incidentally. Anteroposterior roentgenograms frequently suggest defects of the isthmic zone but seldom reveal them as plainly as those demonstrated in figure 1 *a* and *b*. Fairly frequently defects of the isthmic zone are not detectable at all in the anteroposterior views. When they are seen they show up just inferiorly to the shadow cast by the pedicles The lateral roentgenogram shows a higher percentage of defects of the isthmic zone than does the anteroposterior view, provided the defects are large enough and in the right plane; unilateral defects usually are obscured. The defects, as shown in the lateral roentgenogram figure 2 *a* and *b*, are large and are associated with spondylolisthesis, grade 1 (on the basis of 1 to 4, in which 1 designates the least and 4 the greatest degree of spondylolisthesis) (Meyerding). The oblique or three-quarter view is extremely important in determining the diagnosis, and it is seldom that a defect cannot be demonstrated in this view, if present. The superior articular process, the isthmic zone and the inferior articular process show a "bow tie"[6] shadow on the roentgenogram, and the isthmic zone or the center of the "bow tie" is especially demonstrable in the oblique view. The "bow tie" extends over the intervertebral space below the lumbar vertebra to which it belongs. Defect of the fourth and fifth lumbar vertebrae are demonstrated in figure 3 *a* and *b*, and a defect of the fifth lumbar vertebra with sclerosis and irregularity suggesting an osteochondritic process is demonstrated in figures 4 *a* and *b*. The defect shown in figure 6 *a* and *b* is angulated and outlined with sclerotic bone suggestive of a traumatic origin. The bilateral defects demonstrated in figure 5 *a*, *b*, *c* and *d* are so large that they could be classified as a congenital defect. It is probable that the defect shown in figure 7 *a* and *b* is a congenital one involving the fourth lumbar vertebra with additional localized hypertrophic changes of the fourth and fifth lumbar vertebrae.

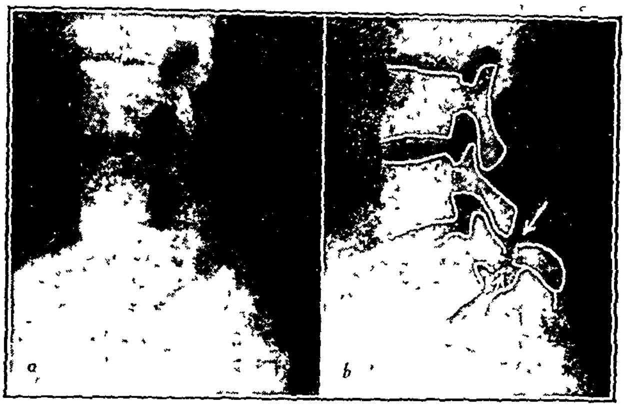

Fig 2—*a*, lateral view demonstrating defect of pedicle of fifth lumbar vertebra; the separation is obvious; *b*, same as *a* but outlined so as to stress the defect of the pedicle.

Fig 3—*a*, left oblique view demonstrating defects of the isthmic zone of the fourth and fifth lumbar vertebrae, *b*, defects outlined

The majority of our patients have been treated conservatively with supports to the back, rest, sleeping on a firm bed, application of heat and massage to the back and exercises to strengthen the muscles of the back. Patients who have not responded to conservative treatment have made good progress following fusion of the spinal column by means of double bone grafts inserted over the portion in which the defect is situated, an operation which has been described by one of us (Meyerding). Defects of the isthmic zone are also one of the criteria for bone grafting in cases in which surgical removal of a herniated disk is done.

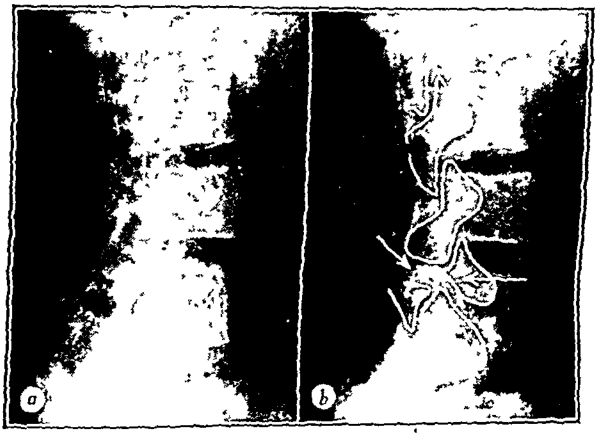

Fig 4—*a*, left oblique view demonstrating sclerosis and irregularity of the fifth lumbar vertebra; *b*, outlined to show "bow tie" defect of fifth lumbar vertebra

COMMENT

We have attempted to call to the attention of the medical profession a fairly common lesion of the spinal column that is responsible for low back pain and to reemphasize the importance of the oblique roentgenogram in determining the diagnosis in cases in which the patient has obscure backache and a weak, unstable back. Treatment is directed toward increasing the stability of the lower part of the spinal column.

REPORT OF ILLUSTRATIVE CASES

The following patients complained of low back pain and were seen at the Mayo Clinic during routine examination, which revealed typical defects of the isthmic zone.

Case 1—A housewife aged 36, seen in October 1944, complained of low backache of four and a half years' duration. She stated that her symptoms had followed a fall in which the shoulder received most of the injury, that the pain was an aching type and was limited to the lumbar and left sacroiliac regions *with occasional extension to the left leg*, that the pain was aggravated by sitting, and that she would get a catch in the lower part of the back when rising from a stooping position. She had no aggravation of the symptoms on coughing or sneezing and no morning stiffness.

The laboratory examination of urine and blood and roentgenograms of the spinal column and pelvis gave negative results

---

[6] Galluccio, A. C.: Spondylolisthesis: A General Consideration, with Emphasis on Radiologic Aspects, Radiology 42: 143-158 (Feb.) 1944.

The patient was sent home to try conservative treatment consisting of reduction of weight, baking and massage to the back and the use of a lumbosacral support. Three and a half months subsequently she returned with the same complaints. Anteroposterior roentgenograms at this time revealed an apparent defect of the isthmic zone of the fifth lumbar vertebra, which was confirmed by oblique roentgenograms. Following neurologic consultation, an exploration for protruded intervertebral disk was performed by the neurosurgeon with negative findings. After this a double bone grafting procedure was carried out by the orthopedic surgeon to produce a fusion of the lumbosacral segment of the spinal column. At three and a half months postoperatively, too early to evaluate the final result, the patient has obtained definite relief of symptoms.

CASE 2.—A nurse aged 45, seen in February 1945, complained of low back pain which had been present all her life. She stated that she had undergone hysterectomy eight years prior to her admission but that there had been no relief from her backache, which had become more severe during the six months before examination, and she had had occasional extension of pain to the left thigh and leg. Examination gave negative results except for a slight diminution of the left ankle jerk. The laboratory examination of the blood and urine revealed negative findings. The roentgenograms showed defects of the isthmic zone of the fifth lumbar vertebra with spondylolisthesis, grade 1. There was considerable separation of the neural arch plainly demonstrated in the lateral roentgenogram. The patient is receiving conservative treatment consisting of heat and massage, rest and the use of a lumbosacral corset, from which she has derived considerable benefit. Lumbosacral fusion has been advised if aggravation of symptoms occurs.

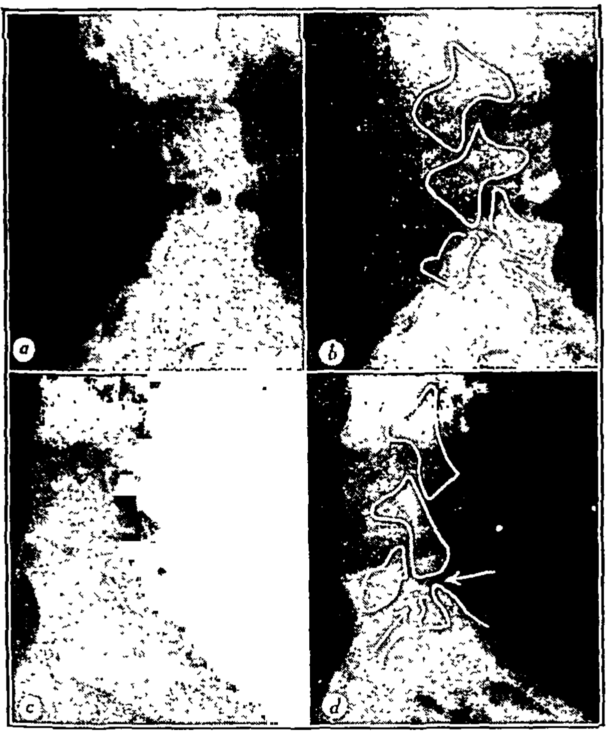

Fig. 5.—*a*, left oblique view demonstrating a large defect of the isthmic zone of the fifth lumbar vertebra; *b*, same as *a* with defect outlined; *c*, right oblique view showing large defect of the isthmic zone of the fifth lumbar vertebra; *d*, same as *c* with defect outlined.

CASE 3.—A man aged 44, a worker in a dry cleaning establishment, seen in January 1945, complained of low back pain which had troubled him for about twelve years and had become more severe and constantly present during the two years just prior to admission. He stated that several years prior to his admission he had had slight pain down the right leg but that he had none at the time of admission. The attacks of pain had never confined him to bed, but they had interfered with his work. He said that he slept better on the floor than on his bed and that the pain was worse on exertion or strain and was relieved by rest. Examination of the back revealed muscle spasm and limitation of motion; that of the lower extremities gave normal results. Laboratory examination of the blood and urine revealed negative results. The roentgenograms revealed defects of the isthmic zone of the fourth lumbar vertebra with spondylolisthesis grade 1 of the fourth lumbar vertebra on the fifth. The disk interspaces were explored by a neurosurgeon, at which time the only positive findings were slight thickening of the ligamentum flavum and extreme mobility of the neural arch of the fourth lumbar vertebra. Following this part of the operation a double bone grafting procedure to produce a fusion of the last three lumbar vertebrae to the sacrum was performed by the orthopedic surgeon. Though it is too early to report the final results, the patient has made a satisfactory convalescence to date.

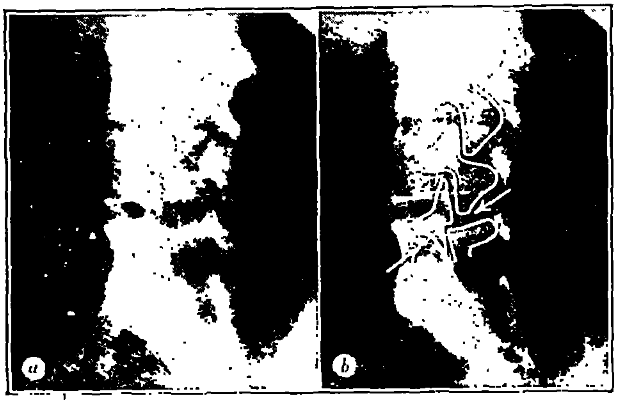

Fig. 6.—*a*, right oblique view demonstrating a defect of the isthmic zone of the fifth lumbar vertebra with sclerotic change; *b*, defect outlined.

CASE 4.—A farmer aged 33, seen in February 1945, complained of attacks of low back pain for many years' duration. He said that he would have two or three severe attacks each year but that there had been no extension of the pain to his legs until he sustained a fall about a month prior to admission. After this fall he had had pain down the left leg to the foot for the first time. The laboratory examination of the blood and urine gave negative results. The oblique roentgenograms revealed defects of the isthmic zone of the fourth lumbar vertebra. The exploration was performed by a neurosurgeon, and a protruded intervertebral disk, fifth lumbar vertebra, was removed. After this part of the operation was completed, the orthopedic surgeon performed a double bone graft to produce a fusion of the lumbosacral segment of the spinal column. The patient has made satisfactory progress, with apparent relief of symptoms at the time of the writing of this paper.

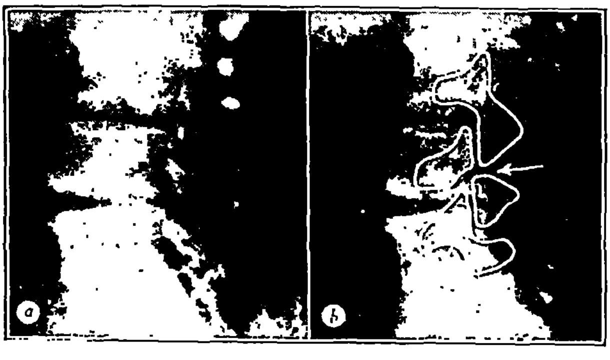

Fig. 7.—*a*, right lateral view demonstrating congenital defect of the isthmic zone of the fourth lumbar vertebra with hypertrophic changes of the fourth and fifth lumbar vertebrae showing anteriorly; *b*, defects outlined.

Case 5.—A man aged 50, a hardware clerk, seen in March 1945, complained of constant low backache with extension of pain to the iliac crests, which had followed a fall on the flat of his back about six months prior to his admission at the clinic. He stated that there had been no extension of pain to the legs but that heavy lifting and stooping caused aggravation of his symptoms, that he had had more pain when sitting than when standing and that heat, rest and wearing of a supporting corset had helped to some extent. The laboratory examination of the blood and urine gave essentially negative results. The oblique roentgenograms revealed defects of the isthmic zone of the fifth lumbar vertebra with spondylolisthesis grade 1. The patient elected a trial of conservative treatment, which is being carried out at the time of the writing of this paper.

Case 6.—A carpenter aged 53 gave a history of a fall of 20 feet three years prior to his admission, at which time the back was injured and since which time he had had constant dull aching pain, stiffness and soreness of the lower part of the back. He said that the pain in the back was aggravated in direct proportion to activity and stress placed on the back, that it was worse at night than in the morning and that there had been no extension of pain to the legs. The examination of the back gave essentially negative results. The laboratory examination of the blood and urine gave negative results. The oblique roentgenograms of the lumbar segment of the spinal column showed defects of the isthmic zone of the fourth lumbar vertebra. The patient is having conservative treatment, consisting of baking and massage. The avoidance of excessive activity, of jarring and strain of the back and of trauma was advised.

Case 7.—A housewife aged 35, seen in March 1945, stated that she had had backache for the first time following a fall down a basement flight of stairs about five years prior to her admission at the clinic. She said that about two years prior to admission the pain in the lower part of the back began to extend down the buttock and into the thigh and that ten months before she came to the clinic it became more constant in character and exertion and strain aggravated it. She also said that it was worse when she was fatigued or after sitting for a time but that the pain in the leg was minimal. The laboratory examination of the blood and urine gave negative results. The physical examination was essentially negative. In this case the anteroposterior, lateral and oblique roentgenograms revealed defects of the isthmic zone and spondylolisthesis grade 1. The oblique roentgenograms revealed bilateral open neural arches of the fifth lumbar vertebra. An exploration at the lumbosacral interspace for a protruded intervertebral disk was found negative by the neurosurgeon. After this part of the operation the orthopedic surgeon performed a double bone graft to the lumbosacral segment of the spinal column; the grafts extended from the third lumbar vertebra to the sacrum. The patient has been making satisfactory progress to date.

Effects of Closed Cranial Injuries.—In about 11.5 per cent of the fatal cases of injury to the head there is found at autopsy some evidence of injury to the upper brain stem in the form of compression, distortion or hemorrhage in the tegmental or basilar portions or both. Such lesions may be the result of general disturbance (traumatic shock to the head, air or fat embolism), of local pressure (by extramedullary hemorrhage) or regional injuries (basal fractures or penetrating foreign bodies), of sudden lateral dislocations of the brain mass, of a coup-contrecoup mechanism (falls or projections on the back of the head), of the effects of pressure from one or both sides by a swollen and/or dislocated temporal lobe (extradural or subdural hemorrhage, subdural fluid accumulation, severe contusions or hemorrhages of the temporal lobe with consequent edema or edema alone) or, finally, of a combination of two or more of these mechanisms. In some cases the vascular lesions may be predisposed to irregular development (vascular anomalies, hypoplasia) or to disease (syphilis, arteriosclerosis). In a few cases the situation may defy analysis and the exact mechanism remain an enigma.—Courville, Cyril B.: Effects of Closed Cranial Injuries on the Midbrain and Upper Pons, in Trauma of the Central Nervous System, Baltimore, Williams & Wilkins Company, 1945.

Clinical Notes, Suggestions and New Instruments

DYSPNEA IN HEMOPHILIA FROM HEMORRHAGE INTO LARYNX

J. ROBERT FOX, M.D.; J. T. SPENCER, JR., M.D., AND
L. M. TOCANTINS, M.D.
Philadelphia

Hemorrhage from the lower respiratory tract is a relatively rare occurrence in hemophilia. Little stress, however, has been placed on the fact that involvement of the pharynx and larynx by blood extravasations beginning at or above these organs are not uncommon in these patients. Occasionally the extent of the hemorrhage may be such as to interfere with phonation, swallowing and even breathing. In 2 of the instances herein recorded strenuous use of the voice preceded the onset of the manifestations. Hemophilic hemorrhages commonly follow muscular exertion. Even in normal persons, excessive and loud use of the voice may be accompanied by hemorrhage and edema of the larynx,[1] which usually disappear with rest. These observations suggest that in hemophilic patients this type of hemorrhage may take an exaggerated form and progress to the point of producing serious obstruction to the air and food passages.

REPORT OF CASES

Case 1.—R. D., a white man aged 30, an insurance adjuster, admitted to the bronchoscopic ward of the Jefferson Hospital to the service of Dr. L. H. Clerf because of shortness of breath, coughing and inability to talk, had a serious argument two days previously with a recalcitrant customer and attempted to "talk the other man down" for most of the afternoon. He spoke in a loud tone for a total period of time of about four hours. That evening his throat felt a little sore, and the next day the soreness increased. He had some difficulty in swallowing and was somewhat short of breath. He attributed these symptoms to a mild respiratory infection, though he had no fever or any other constitutional symptoms. On admission to the hospital two days after the onset of the symptoms, he was having paroxysmal attacks of cyanosis and dyspnea. The mouth secretions had to be expectorated, since attempt to swallow caused a spill into the trachea followed by painful coughing.

The patient's temperature was normal, and mirror laryngoscopy showed the vocal cords immobilized in a position of adduction. The arytenoids and aryepiglottic folds were greatly swollen and dark, indicating the presence of a hemorrhagic process in the entire posterior larynx. There was no external swelling of the neck or tenderness on palpation. Because an acute infection was thought to be responsible, he was given penicillin and fluids intravenously. The patient had not told the physician that he was hemophilic. The hemoglobin on admission was 84 per cent and the red blood cell count 4,000,000.

Three hours after admission it was necessary to perform a tracheotomy. A number 5 tracheotomy tube relieved the dyspnea, but the tissues which surrounded the wound continued to bleed actively for several days. Repeated interrogation then elicited from the patient the written statement that he was hemophilic. This was later confirmed by other members of his family, who said that he and one brother had had in the past several episodes of bleeding requiring transfusions. Studies of his blood revealed a venous clotting time of three and one-half hours (glass tube) and of five hours (collodion coated tube). The plasma prothrombin was 100 per cent of normal. The swelling of the tissues of the neck continued to increase until it reached the appearance illustrated in figure 1.

Between June 3 and June 17, 1945 the patient received the following intravenously:

Isotonic plasma, four infusions of 500 cc. each. Citrated whole blood, six infusions of 500 cc. each and one infusion of

---

From the Departments of Laryngology and Medicine, Jefferson Medical College and Hospital.

[1] Clerf, L. H.: Personal communication to the authors.

1,500 cc. Red blood cell suspension, four infusions of 1,000 cc. each and one of 500 cc. A total of 11,000 cc. of blood or blood substitutes was given. By the fourth day after the tracheotomy the neck began diminishing in volume, and by the seventh day some air was passing through the larynx. On the tenth day the tracheotomy tube was corked, and on the eleventh day the tube was removed. Healing of the tracheotomy wound was unusually slow; by July 13 the lips of the wound were still apart. Bleeding did not stop permanently until twenty-three days after the wound was made.

Case 2.—N. F., a man aged 31, Italian, a laborer, known to be hemophilic for twenty years, reported to work feeling well on Jan. 12, 1943. A new man was assigned to work with him on a long machine and, since he was inexperienced, required frequent directions. Because of the great din in the shop the patient had to shout his directions to him to be clearly heard at the other end of the machine. This shouting continued off and on for about three hours, when he began to feel some soreness in the throat and difficulty in swallowing. He then stopped the shouting but gradually became hoarser and felt his neck swelling. When he left the plant in the afternoon he could hardly speak. At 2 a. m. he was awakened with a sore throat and felt that his neck was more swollen. He had a sensation of a lump on either side of the throat. He was admitted to the medical ward of the Jefferson Hospital, service of Dr. H. A. Reimann, the day following the onset of the disease. He had a slight leukocytosis and a temperature of 100 F. The venous blood coagulation time was two hours and twenty-five minutes (glass tube); the hemoglobin, red cell and platelet count were normal. Laryngologic examination revealed what appeared to be an acute laryngitis and swelling in the region of the epiglottis. This swelling was so great that it was considered wise to introduce a nasal feeding tube at this time. Roentgenologic examination of the neck showed a soft tissue density between the lower mandible and the hyoid bone. This soft tissue mass was apparently depressing the hyoid bone and also infringing on the air space of the hypopharynx. The clinical impression was hemophilic hematoma of the soft tissues of the neck in the region of the epiglottis. Because there had not been much loss of blood, a transfusion of 500 cc. of two day old citrated blood was given after removing 500 cc. of blood from the patient. He was given a liquid diet and cautioned not to talk. Improvement began about a day after the transfusion, much of the tenderness, hoarseness and swelling disappearing gradually. Simple inspection of the throat at this time revealed large hemorrhagic areas about the posterior pillar of the tonsils, which had not been present at the time of admission and probably represented a dissecting spread of the extravasated blood.

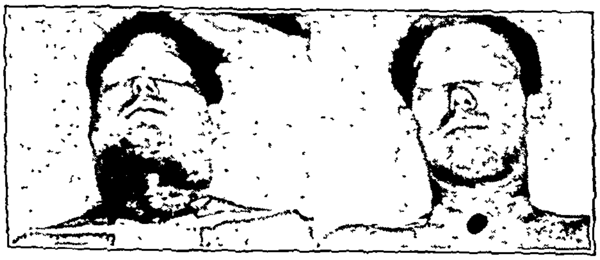

Fig. 1 (case 1).—Left, appearance when the swelling of the neck was at its highest. Right, appearance ten days later.

COMMENT

These 2 patients demonstrate perhaps two different degrees of involvement of the larynx and adjoining tissues by edema and hemorrhage. The cause of the bleeding could be traced in both instances to overuse of the voice. That hemorrhage so initiated may, in this location, constitute a serious threat is probably not generally recognized. It is understandable that, at first sight, an infectious process may seem to be the cause of the disorder. The lack of serious constitutional symptoms and, as in case 1, the absence of fever indicate a noninfectious disorder.

Deep seated hematomas in the neck region leading substantially to the same problem encountered in these patients have been described following dental extractions in the hemophilic. Endicott, Mitchell and Qvist[2] reported asphyxia and death in a hemophilic due to massive hemorrhagic infiltration of the floor of the mouth. These authors traced the path of the extravasation of blood in their patient, who had had an extraction of a second right lower molar tooth and died sixty-six hours later. According to Endicott and his co-workers[2] the blood extravasated from the floor of the mouth and dissected downward through the base of the tongue in the plane above and behind the mylohyoid muscle and the hyoid, thus reaching the submucous tissues of the aryepiglottic region and thence the submucosa of the larynx.

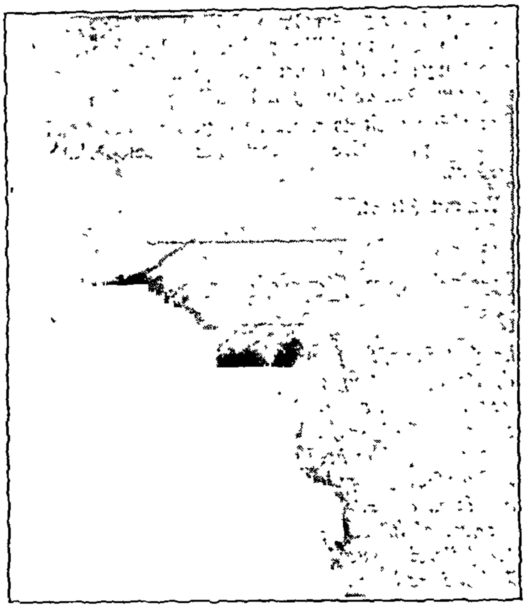

Fig. 2 (case 2).—Lateral view one day after admission. Note downward displacement of hyoid bone by soft tissue mass below the mandible.

In instances similar to the case reported by Endicott and his co-workers[2] the hemorrhagic and traumatic nature of the infiltration into the deep cervical tissues is clear. When the hemorrhage, however, starts in the deep tissues themselves, as for example in a muscle mass, the true nature of the process may not at first be evident. Hematomas in the larynx may result from violent abuse of the voice, as in singing, shouting or screaming.[1] These hematomas, which are not absorbed as a rule, become, if left alone, organized into a small firm tumor that has been called a fibroangioma.[3] A form of hemorrhagic involvement of the larynx following violent and prolonged use of the voice has been described as "hemorrhagic laryngitis," though inflammation may or may not be present. The condition has been observed in hemorrhagic disorders[3] but, so far as we know, not to the alarming degree noted in our 2 patients. The cases herein reported demonstrate that such excesses may lead to serious complications in a hemophilic person and that the disorder may not necessarily be a complication of an infectious state. Whether the hemorrhage starts in the vocal cords themselves or spreads into them from adjoining structures is difficult to determine. It is possible that the hemorrhage actually comes originally from the accessory muscles of the larynx, which during loud and prolonged shouting would be put under excessive strain.

It is wise, therefore, to include among the recommendations for the management of hemophilic patients that they refrain from excessive or strenuous use of the voice. This caution is in line with the usual recommendations against muscular excesses of any type in these patients. It is likewise important to bear in mind that a "hemorrhagic laryngitis" in a man may be a manifestation of a congenital or acquired disorder of hemostasis. Whenever possible, if the patient is hemophilic a small citrated blood transfusion should be given early. This would check the bleeding, prevent the spread of the hemorrhage and thus render a tracheotomy (with its attending risks in a hemophilic patient) unnecessary.

---

[3] Jackson, Chevalier, and Jackson, C. L.: The Larynx and Its Diseases, Philadelphia, W. B. Saunders Company, 1937.

SUMMARY

1. In 2 hemophilic patients hemorrhage in and about the larynx and adjoining structures followed loud and prolonged shouting. In 1 hemophilic patient asphyxia was prevented by tracheotomy; in the other the spread of the process was apparently arrested early by a blood transfusion.

2. Hemophilic patients must be cautioned not to abuse their voices as a preventive against the development of these complications.

Council on Foods and Nutrition

If the full benefit of any public health measure is to be realized, its application must be widespread and continuous. There are many indications that interest in and use of iodized salt by the medical profession and the public is waning to a point where the public health may suffer as a result. In order that the benefits of regular usage of an iodine containing salt may be pointed out once again and the importance of the need for a renewal of interest stressed, Dr. Kimball has kindly prepared the following review of the subject at the request of the Council. This has been authorized by the Council for publication.

George K. Anderson, M.D., *Secretary.*

IODIZED SALT FOR THE PROPHYLAXIS OF ENDEMIC GOITER

O. P. KIMBALL, M.D.
Cleveland

It is necessary again to review the problem of goiter prophylaxis. There are ample data proving that endemic goiter can be prevented and simple, practical methods of prevention are known. The present need is to place this important public health problem under the proper authority so that it will be continued generation after generation.

The prevention of endemic goiter in man on a large scale was begun in 1916. This research was started through the public schools in Akron, Ohio, by Marine and Kimball and was described in detail at that time.[1] By 1920 it had been shown most convincingly that endemic goiter in adolescent girls could be prevented by keeping the thyroid saturated with iodine. From 1920 to 1924 many cities both in the United States and abroad were carrying out parallel programs for the prevention of goiter.

During these same years an improved method for determining minute quantities of iodine was developed, and by 1924 the water in our endemic goiter regions had been analyzed. In Michigan analyses were made of food and water throughout four counties diagonally across the state, namely Houghton, Wexford, Midland and McComb, and the resulting data were used as representative of conditions throughout the state. Final conclusions were that the amount of iodine in the water supply is an accurate index to the food iodine found in that section.[2]

The iodine content of the water in Houghton County was found to be "nil" and 64.4 per cent of all the school children in this county had distinct thyroid enlargement or simple goiter. In Wexford County the iodine content was 0.5 part per billion and the incidence of goiter was 55.6 per cent. In Midland the iodine content was 7.3 parts per billion with the incidence of goiter 32.7 per cent and in McComb County, where the iodine content was the highest, namely 8.7 parts per billion, the incidence of goiter was only 26 per cent. In these counties there were 65,537 children examined and the incidence of simple goiter was 38.6 per cent. This was considered the average for the state of Michigan. The results of this survey showed beyond a doubt that there is a direct relationship between the scarcity of food iodine and a high incidence of simple goiter.[2]

The Michigan State Department of Health and the Michigan State Medical Society made the first organized effort to prevent goiter by the use of iodized salt.[3] The salt producers agreed to make a table salt containing potassium iodide 0.02 per cent. The wholesale grocers agreed to handle, as far as possible, only iodized salt for table use. The cost of this iodine was borne equally by the producers and by the wholesale grocers, so that the cost to the consumer was the same as for the ordinary table salt. Neither the manufacturer nor the wholesale grocer was to advocate the use of iodized salt or to advertise it in any way. Promotion was left entirely to the state department of health and to the medical profession. Lectures, newspaper articles, radio talks and placards in every school explained briefly the thyroid gland, its function and chemistry. The dependence of normal thyroid function on iodine was stressed, and the deficiency of iodine as the sole cause of endemic goiter was repeatedly emphasized. This campaign resulted in the use of iodized salt in approximately 75 per cent of the homes in Michigan beginning in May 1924.

As was expected, there were a few papers written by medical men expressing anxiety and fear lest the use of iodized salt produce toxic goiters. Because of these few articles, which made some startling claims, it was necessary in 1927 and 1928 to make a resurvey throughout the same counties in Michigan, both to learn the efficiency of iodized salt and to determine any harmful effects from its continued use.[2] It was necessary to study adults with goiters to see if any had become toxic from the use of iodized salt during the previous four years. To this end the county medical society in three counties in Michigan and the state health department arranged clinics in which 1,229 adults with long-standing goiters were studied. Of this number 4.1 per cent of those who had used iodized salt continuously for four years had developed symptoms of toxic goiter, while 55.5 per cent of those who had purposely avoided its use were found to have toxic goiter. Stated briefly, the use of iodized salt was a very efficient and practical method of goiter prophylaxis and found to be entirely safe.[2] This survey also included a study of over 50,000 children in the same schools where four years previously we had examined 65,000. The results were as follows: In Wexford County the incidence of goiter had dropped from 54.6 per cent in 1924 to 17.2 per cent in 1928; in Midland County the incidence had decreased from 32.7 per cent to 8.8 per cent; in the city of Grand Rapids, where in 1923 the incidence of goiter was 30 per cent, in 1928 it was down to 9 per cent. Throughout this resurvey not a child was found who showed the slightest ill effect from the use of iodized salt.

[3] Kimball, O. P.: Endemic Goiter and Public Health, Am. J. Pub. Health 18:587 (May) 1928.

Even though it had been only four years since our original program of education, it was necessary to campaign again throughout the state, emphasizing the good results and the safety of this prophylactic measure. Again in 1934 and 1935 the school physicians were reporting an increase in the number of small colloid goiters in children. Simultaneously the wholesale grocers reported a decrease in the percentage of iodized salt consumed in Michigan. There was a renewal of the fear of using iodized salt and a return of the same question—why use a "medicated" salt? This question had been answered in every published article on goiter prevention and every school placard throughout the state, but this type of education seems to last for only a few years and each generation has to be told again.

The last survey was made in 1936 and included the same four counties of Michigan and the city of Grand Rapids. In this study 61,429 children were examined. The incidence of goiter had dropped from the original figure of 38.6 per cent in 1924 to 8.2 per cent. Among those using iodized salt regularly the incidence of goiter was only 2.88 per cent. A valuable study was possible in the comparison of two cities, Houghton and Calumet, in Houghton County.[4] These two cities were only 30 miles apart; consequently the natural factors determining goiter would be the same. However, the percentage of goiter in Houghton High School was 12.12 and in Calumet High Schools 28.72. Calumet is a mining town, and approximately two thirds of the families were on relief during the years 1932 to 1935 and only noniodized bag salt was furnished to families on relief. In the period of three years with the only source of food iodine closed to the homes on relief, goiter was seen to be proportionately as prevalent as ever.

The incidence of goiter among the school children of Cleveland in 1924 was 31 per cent. In this community, however, the prevention of goiter and especially the generalized use of iodized salt had been frankly and repeatedly criticized. There was such a widespread fear of the so-called "dangers of iodized salt" that less than one half of the homes in Cleveland ever used it. In 1937 a resurvey showed the total incidence of goiter to be 18.5 per cent. Among those using iodized salt regularly it was 7.7 per cent, and among those not using it at all the incidence of goiter was 30.7 per cent, or practically the same as in 1924, before any preventive measures had been introduced.[5]

At present, 1945, ten years have elapsed since the last organized study and campaign for goiter prevention. No such study or campaign is being considered at present. The only information available is in the clinical studies and personal findings of physicians interested in the prevention of goiter. During the past two years, in examining school children in Detroit and Cleveland, I have found numerous small or moderate sized goiters. These were the typical hyperplastic thyroids or colloid goiters found so frequently among adolescent children of this area before prophylaxis was started. In each case they definitely were not using iodized salt and had not used it for one or more years. In some instances there was the same prejudice against "medicated" salt, while in the majority of cases they had just forgotten to demand it. Several families had decided that, since nothing had been heard about goiter prevention for several years, they concluded the "epidemic" was passed and therefore purposely used plain salt.

Complete information on the amount of iodized and plain salt used each year is not available. The only information obtainable is the statement by the salt producers that the percentage of iodized salt consumed has gradually decreased during the past four or five years.[6]

In spite of the many surveys in this country and abroad there appears to be no cumulative knowledge among the general population about the cause and prevention of endemic goiter. Furthermore, there is an abundance of data on the efficiency and safety of iodized salt as the means of prophylaxis; yet the consumption by the general public gradually decreases unless repeated campaigns are made by state health departments to encourage its use.

After the last survey in Michigan in 1936 it was strongly urged that each state where goiter is endemic should make a similar campaign of education every ten years.[5] No such effort has been put forth by a single state.

The ideal method would be the same form of goiter prevention the people of West Virginia enjoyed until 1900 or, more accurately, until the salt companies of Ohio and Michigan produced a refined table salt and promoted its sale throughout the state.[3] Prior to that date there was no endemic goiter in West Virginia, but by 1922 the evidence of endemic goiter was as high as in the Lake Superior region: around 60 per cent of adolescent girls had goiter. According to records and information from the older physicians there were, prior to 1900, no toxic adenomatous goiters and only rarely did they encounter a case of toxic diffuse goiter. There had been no effort to prevent goiter in this section, but fortunately the only salt was a natural, unrefined salt commonly spoken of as a coarse brown salt. In 1924 analyses showed that this unrefined salt contained iodine equivalent to 0.01 per cent potassium iodide.[3] It was this natural unrefined salt of the Kanawa River Valley in West Virginia, with the perfect record of prevention of endemic goiter, which set the pattern for the so-called iodized salt.

My recommendation would be that the American Medical Association, the American Public Health Association and the Federal Food and Drug Administration cooperate to give the entire country a natural salt containing 0.01 per cent potassium iodide or its equivalent. The term "iodized" should be eliminated at once and emphasis be placed on the use of a whole salt or natural salt to prevent food deficiencies. The need is for only one kind of salt and this standardized so that it contains the important food elements which are found in the natural unrefined salt. The "prevention of endemic goiter" will then be as nearly completed as any public health measure can ever be.

DECOMPRESSION SICKNESS

Students of aviation in World War II have focused their attention on a series of symptoms which may manifest themselves at altitudes as low as 35,000 feet and which are unrelated to such obvious causes as lack of oxygen, ear and sinus trouble or intestinal pains. These symptoms, grouped under the term "decompression sickness," vary from a mild rash, hyperesthesias, anesthesias or tightness in the chest to more severe manifestations such as excruciating pain about the joints, severe cough, convulsions, paralysis and syncope. These symptoms are well known to divers and caisson workers and are referred to by them as "bends," "chokes," "itch" and "staggers." Compressed air illness is due to bubble formation in the blood and body tissues; symptoms of caisson disease can be readily alleviated by recompressing the patient and then decompressing more slowly. Experience at simulated high altitudes likewise indicates that recompression to lower altitudes (even a change from 35,000 to 25,000 feet) will also instantly relieve bends and chokes but that on immediate reascent the pain will reappear in exactly the same place.

According to Harvey[1] the tendency for bubbles to form depends on two factors: on gas dissolved and on pressure in the liquid. He demonstrated in experiments that bubbles must arise from gas nuclei sticking to or forming on or within the endothelial linings of the vascular system or extravascular spaces; only when they have enlarged to the point of instability do they pass into the blood stream. Harvey performed experiments on cats in which the animal was anesthetized with pentobarbital sodium. Its abdomen was opened and the viscera were pushed aside, thus exposing a considerable length of the postcava. When the cat was placed in a horizontal position in the altitude chamber and well illuminated, observations could be readily made through the glass observation ports, and bubbles of 0.2 mm. diameter could be seen within the veins. The altitude maintained in the chamber was about 45,000 feet. With the animal at rest, bubble formation was rarely observed in the postcava. However, if the hind legs of the cat were stimulated vigorously, bubbles from limb veins could be observed moving up the postcava, sometimes within five seconds of stimulation. If only one leg was stimulated, the bubbles formed in the leg appeared in veins draining that leg only. This important discovery of the effect of muscle contraction on appearance of bubbles was first made, according to Harvey, by Whitaker, Blinks and their collaborators and has its practical application in the well recognized fact that straining movements and exercise among aviators is the most important predisposing factor for the development of bends and chokes. Harvey points out that muscular exercise must have a beneficial effect in preventing bubble formation by virtue of the vasodilatation and opening of closed capillaries in muscle tissue as well as of the increased circulation and hyperventilation necessary to remove carbon dioxide rapidly from the blood. The relative influence of these two opposing factors—the enlargement of gas nuclei by muscle contraction and the increased gas elimination due to similar activity—will determine how much and how strenuous the exercise can be. Actually, experience has shown that in man preexercise at ground level before ascent, even when combined with oxygen breathing, will completely prevent the appearance of decompression sickness and offers the most effective prophylactic treatment. In man the amount of oxygen breathing necessary has also been shown to depend on the extent of exercise at altitude. Numerous x-ray studies made in altitude chambers have disclosed the presence of air masses in joint cavities, in popliteal fat and in the fascia between muscles. All observers agree that air may be present in these regions without the pain of bends. Gas in popliteal fat and muscle fascia appears most likely to cause pain. Another theory of the cause of pain in bends refers it to the pain of muscle contraction in absence of oxygen described by Sir Thomas Lewis. The fact, however, that local application of pressure or even a blocking of the blood flow by tourniquet above the painful region will relieve bends is contrary to the intravascular embolism theory.

Nervous symptoms are more difficult to analyze. They could be due to gas blocking capillaries of the central nervous system or to gas in nerve sheaths exerting pressure on nerve trunks. Whatever the genesis of the various symptoms, the etiology of decompression sickness has been demonstrated to be due to bubble formation.

BRITISH PROPOSALS FOR SEX EDUCATION

Education on the biology of sex is still limited to but a few of our population. In an address to the annual general meeting of the British Eugenics Society Bibby[1] presented his philosophy of sex education. He outlined briefly the transfer in 1942 of the major part of the work of the British Social Hygiene Council to the Central Council for Health Education, thus giving official support to sex education. He quoted figures indicating that sex education lectures had been given during 1943 and 1944 to audiences totaling approximately 68,000 persons, plus an additional 230,000 attending meetings dealing with venereal diseases. This he describes "quantitatively—fairly satisfactory." Bibby summarized the objectives of sex education as "preparation to live a joyous, well planned and fruitful life." He discounted the value of mortality produced by threats of fire and brimstone. He does not believe that the teaching of biologic facts will of itself assure satisfactory conduct. "Behavior is dependent upon ideals and inspiration as well as upon factual knowledge and intellectual understanding." Here is his philosophy of sex education and its purposes: "That our people should grow up learning the appropriate facts in the best possible way; that their general attitude to sex should be a completely healthy one; that they should draw up for themselves a code of conduct after careful consideration of all the issues involved and should endeavor to behave according to this rationally determined code; and that they should react to the behavior of others with sympathy, tolerance and charity, but without spineless acquiescence in a code inferior to their own."

Bibby places much stress on the belief that children need not be forced but should be introduced to knowledge as fast as they are ready for it; this procedure is generally accepted in the United States and has been well set forth by Swift.[2] His views on the teaching of facts relating to courtship and marriage are also along the general lines accepted in the United States and embodied in such standard works as those of Frances Bruce Strain[3] as well as by numerous other writers, including Rice,[4] Dickerson[5] and Hutton.[6]

Attention is called to the absence of qualified teaching personnel and the necessity for training youth leaders. In closing, Bibby calls for research as a basis of sex education and particularly for a greater amount and degree of accuracy in our conception of the sex knowledge of the people we are trying to educate and of the relative efficiencies of the various technics in sex education. Lastly, he believes that "our scheme of sex education must not be drawn up in vacuo, as if sex attitudes and sex behavior were things fixed and immutable. If it is to be really potent, it must be sex education for our particular social setting." Britain, it would appear, faces precisely the same problems in sex education as does the United States and faces them in just about the same manner.

PRESIDENT TRUMAN SIGNS NEW VETERANS LEGISLATION

On January 3 President Truman signed the bill creating a department of medicine and surgery in the Veterans Administration which was analyzed in THE JOURNAL of January 5, page 38. On the same day representatives of the Veterans Administration and of various organizations interested in the care of the veterans appeared for a conference with the President, the chief point at issue being the determination as to whether or not preference could be given in the selection of medical personnel to men who had had military service. So seriously did President Truman consider this factor that he addressed a letter specifically to General Bradley urging that such preference be given. As might have been expected, representatives of the Civil Service were opposed to the appointment of physicians in higher grades without regard to Civil Service, but General Bradley emphasized the importance of such exceptions if the Veterans Administration is to be supplied with the physicians necessary to carry on its work. Major Gen. Paul R. Hawley was immediately appointed Acting Surgeon General in accordance with the new legislation.

For the first time it will be possible in the administration of medical care to veterans to utilize the services of highly qualified physicians and surgeons and to establish an organization with top ranking specialists in each medical field. The administrator will himself prescribe the qualifications necessary for appointment as a physician, dentist or nurse and this without regard to Civil Service requirements.

The new legislation, with minor modifications, was endorsed by representatives of the medical profession, including official representatives of the American Medical Association.

It is hoped that civilian physicians will do their utmost to make the Veterans Administration effective in rendering a high quality of medical service. For the first time the medical institutions of the administration will become qualified teaching institutions with residencies in the various specialties, thus becoming fully integrated with the system of medical care which has brought medical service of the United States to the highest level available anywhere in the world.

GENERAL PARRAN ADDRESSES HIS OFFICERS

Officers of the United States Public Health Service, including apparently all reserve officers and those who hold appointments in the emergency hospital units that were established during the war, received last week a mimeographed letter, dated December 10, which created amazement and consternation. Here follows this communication:

> *To:* All officers of the Public Health Service
> *Subject:* The National Health Program
>
> Enclosed is a copy of House Document No. 380, which is the full text of President Truman's message to the Congress on a national health program, a subject of the highest importance to every citizen. The message contains a comprehensive analysis of the health problems of the country and recommendations as to the pattern of legislation to deal with them.
>
> It is a source of particular satisfaction to all of us who labor for the public health advancement that this should be the special subject of a Presidential message. For the first time we have the major elements of a national health policy officially stated in comprehensive terms. This has been a goal of all public health workers for many years, and the enunciation of such a policy by the Chief Executive gives the Public Health Service definite objectives for its future work.
>
> On the same day as the message was delivered Senator Wagner introduced (for himself and Mr. Murray) S. 1606, and Representative Dingell introduced H. R. 4730, designed to implement the proposals of the President. In addition, several bills are pending in the Congress dealing with special phases of the President's legislative program. These include the hospital construction bills, the national mental health bills and the stream pollution bills, each of which would impose substantial additional responsibilities on the Public Health Service.
>
> The appropriate executive agencies of the government have been specifically instructed by the President to assist in carrying out his legislative program as presented to the Congress on September 6. The President wrote to the administrator of the Federal Security Agency on October 4 requesting him "to take primary responsibility for legislative measures necessary to carry out the part of my message (Sept. 6, 1945) outlined in section 21 concerning a national health program to provide adequate medical care for all Americans and to protect them from financial loss and hardship resulting from illness and accident."
>
> Every officer of the Public Health Service will wish to familiarize himself with the President's message and will be guided by its provisions when making any public statement likely to be interpreted as representing the official views of the Public Health Service.
>
> THOMAS PARRAN, Surgeon General.

If the fourth and fifth paragraphs of this letter say what they seem to say, the President of the United States has instructed the executive agencies of the government to get behind his legislative program for the extension of health. The Surgeon General of the U. S. Public Health Service goes into action, ties the Wagner-Murray-Dingell bill right into the program and at least hints to his officers that they had better be careful about making any public statements with regard to the message.

Many of those addressed in this instance are physicians in the private practice of medicine in the United States. They volunteered their services in the formation of hospital units to aid the people of this country in an emergency; they continued their membership in the Reserve of the Public Health Service after the war itself ended because it seemed to be desirable to have an emergency service available. If, however, men are to be directed in their thinking or muzzled in their speaking incident to their desire to be of service to the health of the nation, their rights as American citizens will have to prevail. Reserve officers will have to consider seriously whether or not they wish to maintain any official connection with such a federal agency. Incidentally, it might have been better if General Parran had, in these final two paragraphs, said in shorter and clearer sentences exactly what he meant to convey.

Current Comment

AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY

In October 1920 appeared the first issue of the *American Journal of Obstetrics and Gynecology,* successor to a periodical founded in 1868 as the *American Journal of Obstetrics and Diseases of Women and Children.* The issue for December 1945 marks the twenty-fifth anniversary of the new publication. During all of this period it has been under the editorship of Dr. George W. Kosmak, who marks the twenty-fifth anniversary by an editorial which indicates some of the tremendous progress that has been made in the field over that period:

> Knowledge of the physiology of reproduction has advanced greatly, with the attainment in particular of a knowledge of the role of the endocrines, the morphologic development of the embryo and the control of uterine contractility. Gynecologic and obstetric pathology has become an essential part of the personal knowledge of each practitioner of the specialty. The widespread use of blood and plasma has completely altered the outlook in major surgical operations and in obstetric hemorrhage. The sulfonamides and penicillin have revolutionized the treatment of infections. Radiation has been further developed in the treatment of cancer. Finally, the enlistment of the efforts of the practitioner of obstetrics in a great cooperative study has produced a phenomenal improvement in obstetric mortality and morbidity.
>
> Of interest is the fact that the mechanical phases of gynecologic treatment show little change, while the development of medical and physical methods of therapy and diagnosis has assumed such great prominence. While operative technics have been developed and expanded, the scalpel today is less in evidence than the test tube and the experimental or the research laboratory.

Attention is called also to the extent to which governmental funds are now being used for the extension of maternal and infant care. Dr. Kosmak points out that "It is understandable that the fields of obstetric and pediatric practice should be the first to receive such attention" because of the sentimental factors involved; these special fields may, however, serve simply as experimental areas and thus be the forerunner of the extension of government activity in other branches of medicine. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION tenders to the *American Journal of Obstetrics and Gynecology* warm congratulations on twenty-five years of excellent service to the advancement of obstetrics and gynecology.

MEDICINE AND THE WAR

NAVY

PROGRAM FOR TRAINING OF SPECIALISTS

Vice Admiral Ross T. McIntire, chief of the Bureau of Medicine and Surgery, recently announced the establishment of a long term program for the training of specialists, involving the designation of nine large naval hospitals as special centers of instruction. The program will make available to medical officers a complete term of specialization training comparable to the best obtainable in civil life. All of the recognized specialties will be taught, including anesthesiology, dermatology and syphilology, internal medicine, neurosurgery, obstetrics and gynecology, ophthalmology, orthopedic surgery, otolaryngology, pathology, pediatrics, plastic surgery, psychiatry and neurology, radiology, surgery and urology. The nine postgraduate teaching centers will be set up at the naval hospitals at Chelsea, Mass., St. Albans, N. Y., Philadelphia, Bethesda, Md., Great Lakes, Ill., San Diego, Long Beach and Oakland, Calif., and Seattle.

The board of honorary consultants to the Medical Department of the Navy who have actively cooperated in the formulation of the plans and who will assist in their development, are:

Dr. Donald C. Balfour, director of the Mayo Foundation and Clinic, Rochester, Minn.

Dr. Richard B. Cattell, chief of the surgical section, Lahey Clinic, Boston.

Dr. Edwin J. Cohn, department of physical chemistry, Harvard Medical School, Boston.

Dr. Frank P. Corrigan, American ambassador to Venezuela.

Dr. Walter E. Dandy, professor of neurosurgery, Johns Hopkins University Hospital, Baltimore.

Dr. Frank H. Lahey, director of the Lahey Clinic, Boston.

Dr. Oswald S. Lowsley, director of the department of urology, James Buchanan Brady Foundation, New York.

Dr. James E. Paullin, professor of clinical medicine, Emory University School of Medicine, Atlanta, Ga.

Dr. W. Calhoun Stirling, urologist, Washington, D. C.

Dr. Edward A. Strecker, professor of psychiatry, University of Pennsylvania School of Medicine, Philadelphia.

Dr. Meyer Wiener, professor of ophthalmology, Washington University, St. Louis.

Instructors will include not only the regular staffs of the nine special training centers but also members of the Naval Reserve Medical Corps who are prominent in their various fields of medicine and surgery. Present plans call for a definite period of training for the young doctor who enters the Navy on his graduation from medical school. This period would cover one year's internship, one or more years of residency training, two years of sea or foreign shore duty and a definite period of intensive work in this country in that field of medicine which the officer has chosen and which has been approved by the central advisory group.

Internships and residency training will continue to be given at all naval hospitals which are properly accredited, with the more advanced teaching being offered at the nine specialization centers.

NAVAL MEDICAL OFFICERS PRESENTED WELLCOME AWARD

The Wellcome Award, established by the late Sir Henry Wellcome, was recently presented to naval personnel for the sixth consecutive year. Joint recipients of the award were Capt. Joseph S. Barr (MC), U.S.N.R., Newton Center, Mass.; Capt. R. H. Draeger (MC), U.S.N., San Francisco, and Comdr. W. Warren Sager (MC), U.S.N.R., Washington, D. C., for their paper "Solid Blast Personnel Injury," which was selected by the Association of Military Surgeons as the best submitted in the annual competition. The presentation of the honorarium and scroll accompanying the award was made by Capt. Robert E. Duncan (MC), U.S.N., medical officer in command at Bethesda. A gold medal also normally goes to the winner, but the medal has not been cast since the beginning of the war, the die having been destroyed in the London blitz.

Captain Barr is in charge of the orthopedic service at Bethesda, and Captain Draeger is executive officer of the Naval Medical Research Institute. Commander Sager, now on terminal leave, formerly was attached to the surgical staff at Bethesda.

NAVY AWARDS AND COMMENDATIONS

Captain Raymond Webster Hege

A Gold Star in lieu of a second Bronze Star was posthumously awarded to Capt. Raymond Webster Hege, Washington, D. C. The citation accompanying the award was "for meritorious achievement as force medical officer attached to the staff of the commander, First Carrier Task Force, embarked on the U. S. S. *Bunker Hill,* in connection with operations against enemy Japanese forces in the Pacific War Area from Dec. 20, 1944 to May 11, 1945. Responsible for the health and well being of the officers and men of his task force, Captain Hege personally attended the staff and flag allowance personnel on board the *Bunker Hill*; maintaining them at peak of battle efficiency during extended operations against the Japanese Empire, which included the first Tokyo raids, the support of landings on Iwo Jima, strikes against Kyushu and the Kure naval base, support of the Okinawa landings and an engagement with major units of the Japanese fleet on April 7, 1945. Directing all activities under his control with dependable judgment and resource, he worked tirelessly and with brilliant initiative, constantly improving the standards of health within the force and, by his thorough understanding of the peculiar mental and physical needs of men functioning under the strain of continuous combat, skilfully insured the sound health of all force personnel during a prolonged period of intensive operations. By his outstanding professional ability, cool courage and gallant acceptance of extreme danger and hardship, Captain Hege served as an inspiration to all on board the *Bunker Hill,* and his resolute conduct throughout upheld the highest traditions of the United States Naval Service." Dr. Hege graduated from the University of Cincinnati College of Medicine in 1927 and entered the service June 15, 1926. He was killed in action May 11, 1945.

Captain Charles L. McCarthy

A letter of commendation was recently presented to Capt. Charles L. McCarthy, formerly of Washington, D. C., which read as follows:

"Through the courtesy of the Bureau of Medicine and Surgery, U. S. Navy, Capt. Charles L. McCarthy (MC), U.S.N.R., was made available to the Surgeon General's Office, U. S. Army, for work with the Combined Intelligence Objectives Subcommittee. Captain McCarthy was subsequently attached to the Medical Intelligence Branch of the Office of the Chief Surgeon, ETOUSA, to carry out the mission assigned.

"Captain McCarthy's wide general knowledge in the field of medicine and related subjects, and his fluent command of German made his service invaluable to the Combined Intelligence Objectives Subcommittee group. He was placed in charge of the advance section of the Medical Intelligence Branch and thus directed much of the field work carried out, especially that part dealing with uncovering and exploiting targets of opportunity. In addition, he took an active part in the actual investigations.

"Captain McCarthy demonstrated unusual ability and energy and was tireless in his efforts to seek out information. His congeniality and spirit of cooperation enabled him to work well with all the Army personnel with whom he came in contact. It is the desire of this office to express appreciation to Captain McCarthy for his excellent services, and to the Bureau of Medicine and Surgery for making him available for this work."

Dr. McCarthy graduated from Johns Hopkins University School of Medicine, Baltimore, in 1916 and entered the service June 6, 1942.

Lieutenant Commander George William Fox

The Navy Cross was posthumously awarded to Lieut. Comdr. George William Fox, Milwaukee, "for extraordinary heroism as medical officer attached to the U. S. S. *Franklin* following an attack by enemy aircraft near Kobe, March 19, 1945. When his ship was turned into an inferno by an enemy air attack which started violent explosions and raging fires on board, Lieutenant Commander Fox unhesitatingly remained at his battle station in the below-decks sick bay and, despite the penetration of terrific blasts and fumes, steadfastly continued to protect his patients and minister to casualties until he himself succumbed to the dense, suffocating smoke. Lieutenant Commander Fox's valiant and self-sacrificing efforts on behalf of others, his superb courage and unfaltering devotion to duty in the face of grave peril were in keeping with the highest traditions of the United States Naval Service. He gallantly gave his life for his country." Dr. Fox graduated from Rush Medical College, Chicago, in 1931 and entered the service Aug. 17, 1942.

VETERANS

PLANS FOR MEDICAL CARE IN MICHIGAN AND KANSAS

"Home town care of veterans" for service connected disabilities, with free choice of physician, will be offered as a standard practice through an agreement announced by representatives of the Veterans Administration and the Michigan State Medical Society. A similar agreement which would entitle veterans with service connected disabilities to local hospital care for many types of cases also is under consideration, according to representatives of the Michigan Hospital Association.

The agreement will permit veterans to receive treatment and care from local physicians and hospitals. In many cases it will make it unnecessary for veterans to leave families, friends and family physicians to go to veterans' institutions distant from their homes.

Physicians providing service to veterans will be reimbursed through the Blue Cross Plan-Michigan Medical Service, which is a nonprofit prepayment organization established by the medical profession. Michigan Hospital Service, a nonprofit prepayment plan operated by Michigan hospitals, would handle payment for local hospital care provided to veterans under the contemplated hospital portion of the program. In turn, the actual cost to the Michigan Medical Service and Michigan Hospital Service will be repaid by the Veterans Administration. These two organizations are the Blue Cross Plans of Michigan, and similar nonprofit plans are in operation nationally.

Participants in the announcement of the new program in Michigan included Dr. R. S. Morrish, president of the Michigan State Medical Society; Rev. Dr. John Ernst, president of the Michigan Hospital Association; Dr. Stanley W. Insley, president of the Wayne County Medical Society; Guy F. Palmer, Veterans Administrator for Michigan; R. R. L. Novy, president of Michigan Medical Service, and William J. Griffin, president of Michigan Hospital Service.

"The Michigan State Medical Society already has approved this program, but Michigan Medical Service still must hold meetings with physicians throughout the state to invite their individual participation in the program."

"The Michigan Hospital Association also has approved a proposal for local hospital care and it is hoped that an agreement covering this portion of the program will be ready in the near future."

In practice, the program will work much like that by which the Blue Cross now provides hospital and medical services to more than 1,250,000 residents of Michigan. For treatment or care necessitated by service connected disability, the veteran may go to any doctor participating in the program. If it is a case of the type provided by the veterans' program, the Blue Cross will immediately be authorized to make payment for care. Veterans Administration offices will be opened near the Blue Cross headquarters in Detroit so that authorization of payments will not be delayed. Special provisions are planned for veterans of the women's services. Since they cannot be accommodated at present in all veterans' hospitals, it is expected that they will be entitled to local care for both service connected and nonservice connected disabilities.

The schedule of fees which will be paid to doctors already has been approved by the Veterans Administration. This schedule was completed recently after prolonged study by a special committee of the Michigan State Medical Society. Hospitals would be paid the actual costs of providing service under the projected program for hospital care.

The inception of the new veterans' medical and hospital service program occurred at a conference between representatives of Michigan veterans' organizations and of leaders of the Wayne County Medical Society under Dr. Insley some months ago. At this meeting it was suggested that the problem of providing care for veterans might readily be handled through the Blue Cross plans. Agreement on the principles to govern the proposed arrangement was worked out in subsequent meetings with General Bradley, General Hawley and other officials of the Veterans Administration, and details now are being completed.

Kansas

Dr. W. P. Callahan, president of the Kansas Medical Society, has made several trips to Washington conferring with Major Gen. Paul R. Hawley in an effort to come to an agreement with the Veterans Administration on ways in which the doctors of the Kansas Medical Society may provide some of the medical services for veterans of this state. On Friday December 7 Major General Hawley announced the completion of this program and as quickly as possible the plan will be placed in operation in Kansas. The veteran will be permitted to select a doctor of his own choice, who will give an examination to accompany an application for pension. The restriction on this selection rests only on geographic lines in that the veteran will select a doctor from the area in which he resides. According to the agreement with the Veterans Administration, physicians in Kansas may also give medical service, including surgery, for service connected disabilities under certain circumstances primarily if the nearest Veterans Administration hospital is filled. Also under the agreement is the provision that emergencies may be cared for in the community in which the veteran resides. Here again he will have selection of the doctor to do this work.

In return for this the Kansas Medical Society agrees to submit a list of names of doctors qualified to give general examinations and another list of doctors who are specialists in the various fields of medicine. These lists will be submitted to the Veterans Administration, which plans to set up offices near the Kansas Medical Society. Claims will be cleared through that office and then forwarded to the district office for payment. It is expected that this program will go into effect sometime during the month of January.

NATIONAL HOSPITAL FOR SPEECH DISORDERS

The National Hospital for Speech Disorders, New York, is under contract to the Veterans Administration to rehabilitate ex-servicemen with speech and voice disorders. The hospital is also on the list of approved institutions which veterans may attend under the educational provisions of the G. I. Bill of Rights. More than sixty veterans are already receiving treatment at the hospital. While the majority of the veteran-patients are stutterers, several suffer from aphasia caused by head wounds or from aphonia due to loss of the larynx.

ARMY

INVESTIGATE RELEASE SITUATION OF DOCTORS AND DENTISTS

Lieut. Col. Bolling R. Powell Jr. of the Legislative and Liaison Division of the War Department General Staff, and Col. Durward G. Hall, chief of Personnel Service of the Surgeon General's Office, recently departed for Europe to make an exhaustive investigation of the release of army doctors and dentists. A similar investigation was recently completed in the Pacific area.

Colonel Powell and Colonel Hall will determine the medical and dental strength now necessary for each theater so that all surplus professional officers can be immediately shipped out and either be assigned to replace doctors who are eligible for release or returned to civilian life. Another phase of the study will be the determination of the number of hospital beds needed to meet present conditions in the European theaters with the idea of releasing unnecessary beds.

PAMPHLETS FOR PATIENTS WITH PSYCHONEUROSIS

Under the title "What's the Score . . . in a Case Like Mine?" the War Department has issued War Department Pamphlet 20-35, which is given to patients discharged for psychoneurosis. It is a simple statement as to various forms of psychoneurosis, full of inspiration and uplift, with sound advice as to how the discharged soldier shall proceed in civilian life. Copies are available from the Superintendent of Documents, Government Printing Office, Washington, D. C., at ten cents a copy.

NEW COURSE ON CARE OF ARTIFICIAL LIMBS

A new course of instruction in the repair and maintenance of artificial limbs was recently inaugurated at the Walter Reed General Hospital, Washington, D. C., for the purpose of teaching every amputee how to take care of his own prostheses. First suggested by Col. Leonard T. Peterson, the Army's director of research on prosthetics, the program will deal with model limbs and various technical devices and will instruct the amputees in the working and maintenance of their prostheses.

POSTGRADUATE COURSE OF AMERICAN COLLEGE OF PHYSICIANS

A session of the Postgraduate Course of the American College of Physicians was held recently at Barnes General Hospital, Vancouver, Wash., under the direction of Col. Charles K. Berle, commanding officer of Barnes General Hospital. Some of the subjects covered during the meeting were rheumatic fever here and overseas, clinical observation in intestinal infections, massive dosage of penicillin in the treatment of bacterial endocarditis and the roentgenologist and antral gastritis.

ARMY SPECIALIZED TRAINING PROGRAM TO BE LIQUIDATED

According to a recent announcement from the War Department, medical students now in the Army Specialized Training Program, which is undergoing gradual liquidation, will continue training through the current fiscal year, ending June 30, with the future of the program depending on requirements for medical officers, which will be reconsidered at that time.

INSPECTION TOUR OF PACIFIC MEDICAL INSTALLATIONS

An inspection of Medical Department installations in the Pacific is now being made by Brig. Gen. R. W. Bliss, Assistant Surgeon General, Brig. Gen. William C. Menninger, director of Neuropsychiatry Consultants Division, and Dr. Eli Ginzberg, director of Resources Analysis Division. The trip will include stops at Honolulu, Guam, Shanghai, Chungking and Tokyo.

MERITORIOUS SERVICE UNIT PLAQUE

The Meritorious Service Unit Plaque was recently awarded to the 1263d S. C. U. Mason General Hospital, Brentwood, L. I., N. Y. During the period Dec. 1, 1944 to May 31, 1945 this unit performed its duties in a superior manner and demonstrated outstanding devotion to duty. Its accomplishments in the care and disposition of mentally ill patients are considered a noteworthy contribution in the field of military hospitalization and evacuation. Only through enthusiastic and unselfish devotion to duty could such high standards of service be attained. The accomplishments of this unit reflect great credit on itself and the military service. The unit and each of its assigned members are authorized to wear the Meritorious Service Unit Badge.

MALARIA RELAPSE RATE DECLINING

A recent announcement by the Army Medical Department discloses that the hospital admission peak for malaria relapses in the United States was reached in February 1945 with a total of approximately 6,000 cases and has been steadily declining since that time. During 1943, when men began to return from tropical theaters of operations in increasing numbers, the total number of hospital admissions for malaria relapse reached 5,275. By 1944 it had jumped to almost five times that number, 28,150, and in the first six months of this year the total was 30,420.

RETURNS TO SURGEON GENERAL'S OFFICE

Lieut. Col. M. E. Randolph, chief of the eye, ear, nose and throat section at Valley Forge General Hospital, Phoenixville, Pa., was recently transferred to the Office of the Surgeon General, Washington, D. C., to serve as chief consultant in ophthalmology to the Surgeon General. Before being transferred to Valley Forge General Hospital, Colonel Randolph was chief of the ophthalmology branch of the Surgeon General's Office. He will be replaced by Lieut. Col. Phillips Thygeson.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Harold Lynn Wilson

The Legion of Merit was recently awarded to Lieut. Col. Harold Lynn Wilson, formerly of New York, "for exceptionally meritorious conduct in the performance of outstanding services as chief, surgical service, of the 11th Evacuation Hospital semimobile, from Aug. 15, 1944 to May 8, 1945." The citation continued "Lieutenant Colonel Wilson contributed immeasurably to the efficient operation of his unit in the care of battle casualties. Untiring in his efforts to improve constantly the service rendered to the wounded, his usual day was one of eighteen to twenty hours of constant activity during the active phase of combat. Under his supervision large numbers of battle casualties received rapid and efficient treatment. Lieutenant Colonel Wilson's services reflect highest credit on himself and the armed forces of the United States." Dr. Wilson graduated from Cornell University Medical College, New York, in 1927 and entered the service June 1, 1942.

Lieutenant Colonel Gaetano T. DeFusco

The Legion of Merit was recently awarded to Lieut. Col. Gaetano T. DeFusco, formerly of Jersey City, N. J., at present commanding officer of the 183d Station Hospital, Fort Richardson, Alaska, for the performance of exceptionally meritorious services. The citation accompanying the award stated that it was presented "for exceptionally meritorious conduct in the performance of outstanding services during the period May 20, 1943 to Oct. 20, 1945. As regimental surgeon, 78th Coast Artillery Regiment, commanding officer of two station hospitals in the Aleutian area and later as commanding officer, 183d Station Hospital, Fort Richardson, Lieutenant Colonel DeFusco exhibited the highest professional and military standards. In addition to the calm and efficient manner in which he performed his many missions, his ability to perceive future problems, conditions and the initiative and skill to plan in advance and act accordingly was a credit to this command. Lieutenant Colonel DeFusco's personal interest and professional experience were responsible for the establishment of immediate health facilities and a modern dispensary in the town of Unalaska. As a result of his untiring efforts and industry, the medical care for all personnel both military and civilian was carried out in a progressive and exceptional manner. The high standards of efficiency in medical care achieved by the 183d Station Hospital is largely due to the judgment, unselfish energy and devotion to duty displayed by this officer. His high sense of duty and loyalty, combined with professional ability, reflect great credit on himself and the military service." Dr. DeFusco graduated from Georgetown University School of Medicine, Washington, D. C., in 1931 and entered the service in December 1940.

Captain John L. Cathie

Capt. John L. Cathie, formerly of Alexander, N. Y., was recently awarded the Bronze Star "for meritorious achievement in connection with military operations against the enemy at Arawe, New Britain, from Dec. 15, 1943 to March 1, 1944. During the arduous campaign which followed the assault landing on Arawe, Captain Cathie distinguished himself as a squadron medical officer by his outstanding devotion to duty in carrying out his assignment. The squadron aid station was established close to the front lines and he was often exposed to enemy small arms, machine gun and mortar fire while performing his duties. Faced with the problem of providing medical attention for large numbers of men and working under the handicap of a scarcity of medical equipment and supplies, he devoted himself so wholeheartedly to his task that expert treatment was given to troops at all times. Captain Cathie's enthusiasm, his consideration for the welfare of the sick and wounded and his willingness to undergo great physical hardships and personal danger were a priceless inspiration to all the officers and men to the unit in which he served." Dr. Cathie graduated from the University of Toronto Faculty of Medicine in 1937 and entered the service in August 1942.

Lieutenant Colonel John H. Mulholland

Lieut. Col. John H. Mulholland, formerly of New York, was recently awarded the Bronze Star "for meritorious service in connection with military operations as chief of surgical service, 1st General Hospital, European Theater of Operations, from Oct. 23, 1944 to May 1, 1945." The citation further stated that "Lieutenant Colonel Mulholland has given unstintingly of his time and skill, in the professional care of patients, always pursuing new and advanced methods of treatment and thus reducing the rate of mortality among battle casualties treated. As surgical consultant in the Seine section he imparted his knowledge to the surgical services of other hospitals, which resulted in the saving of hundreds of lives and early return to duty of thousands of patients." Dr. Mulholland graduated from New York University College of Medicine, New York, in 1925 and entered the service Oct. 18, 1942.

Captain William M. McConahey Jr.

The Silver Star was recently awarded to Capt. William M. McConahey Jr., formerly of Coshocton, Ohio. The citation accompanying the award called attention to his gallantry on June 22, 1944 in the vicinity of Portbail, France: "When a litter squad of his detachment had failed twice in attempts to evacuate three critically wounded men from an area under heavy enemy mortar concentrations, Captan McConahey himself led the squad forward under the constant enemy barrage. As they approached the wounded men, an enemy machine gun opened fire on the group. Captain McConahey ignored the enemy fire and located and directed the evacuation of each of the three wounded in turn. The gallant example of Captain McConahey resulted directly in the saving of the life of at least one man. His courageous action over and above the call of duty was in accord with high military tradition." Dr. McConahey graduated from Harvard Medical School, Boston, in 1942 and entered the service July 16, 1943.

Captain Emil P. Zarsky

The Silver Star was recently awarded to Capt. Emil P. Zarsky, formerly of Refugio, Texas, "for gallantry in action on Nov. 18, 1944 in the vicinity of Leintrey, France. On notification that two men had been seriously wounded by stepping on a mine, Captain Zarsky, without regard for his personal safety, immediately proceeded fearlessly through the mine field to the scene of the accident. Fully aware of the danger involved, he forbade any one to accompany him, except one officer and one enlisted man. His bravery and unselfish devotion to duty reflect great credit on this officer and exemplify the finest traditions of the United States Army Medical Corps." Dr. Zarsky graduated from St. Louis University School of Medicine in 1929 and entered the service Sept. 22, 1942.

Colonel Claude S. Beck

The Legion of Merit was recently awarded to Col. Claude S. Beck, formerly of Cleveland. The citation stated that Colonel Beck "brought to the Army a wealth of background and training in surgery which he tirelessly imparted to the staffs of the army hospitals. By close and constant supervision over the personnel assigned to the surgical services of the command and over the procedure they carried out, he developed and maintained a high standard of treatment. He was alert and quick to put into use any worth while advances in surgical technic. By his energy, superior professional ability, broad vision and sound judgment, he made a material contribution to the war effort." Dr. Beck graduated from Johns Hopkins University School of Medicine, Baltimore, in 1921 and entered the service Oct. 10, 1942.

Major Julian A. Sterling

Major Julian A. Sterling, formerly of Philadelphia, was recently awarded the Bronze Star. According to the citation, "Major Sterling performed outstanding services in establishing the convalescent training program for this theater. His services included the editing, publishing and distribution of division brochures and the supervision of many convalescent hospital programs. Major Sterling has contributed in great measure to the morale and efficiency of the thousands of wounded soldiers returned to combat and assisted materially in the success of the important theater manpower conservation program." Dr. Sterling graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1936 and entered the service April 1, 1941.

Lieutenant Colonel John A. DePasquale

The Silver Oak Leaf was recently awarded to Lieut. Col. John A. DePasquale, formerly of Hartford, Conn. Lieutenant Colonel DePasquale served on Guadalcanal, the Russell Islands, Rendova and New George. At Rendova he performed operations out in the open, days before the first tents could be put up. Dr. DePasquale graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1936 and entered the service Feb. 24, 1941.

Colonel Guy W. Horsley

Col. Guy W. Horsley, Richmond, Va., was recently awarded the Legion of Merit. He was chief of the surgical service of the 45th General Hospital and the award made was for "exceptionally meritorious conduct in the performance of outstanding services." Dr. Horsley was especially cited for his devotion to duty "during the times of greatest stress immediately following the drive on Rome and the invasion of southern France." Dr. Horsley graduated from the University of Virginia Department of Medicine, Charlottesville, in 1929 and entered the service May 15, 1941.

Lieutenant Colonel Severio Charles Franco

The Bronze Star was recently awarded to Lieut. Col. Severio Charles Franco, formerly of Brooklyn, for "meritorious service in connection with military operations from July 31, 1944 to May 1, 1945." He commanded the Ninth Field Hospital, which was awarded the Meritorious Service Unit Plaque. Dr. Franco graduated from Long Island College of Medicine, Brooklyn, in 1931 and entered the service Sept. 18, 1942.

Captain Seymour Hershman

Capt. Seymour Hershman, formerly of Chicago, was recently awarded the Bronze Star "for meritorious service in connection with military operations against an enemy of the United States during the period July 17, 1944 to April 28, 1945. Captain Hershman, serving as assistant to chief of surgical service, 109th Evacuation Hospital, distinguished himself by his outstanding performance of duty. The high degree of professional skill he displayed, his resourcefulness and loyal, untiring devotion to duty reflect great credit on himself and the military service." Dr. Hershman graduated from the Chicago Medical School in 1942 and entered the service Oct. 6, 1942.

Major Wesley B. Oliver

Major Wesley B. Oliver, formerly of Belvidere, Ill., was recently awarded the Bronze Star for a "display of fine administrative ability, indefatigable energy and tireless devotion to duty, all of which were of inestimable value in the prompt and efficient evacuation of Third Army casualties." Dr. Oliver graduated from Northwestern University Medical School, Chicago, in 1936 and entered the service Sept. 2, 1942.

Lieutenant Colonel William T. Holladay

The Legion of Merit was recently awarded Lieut. Col. William T. Holladay, formerly of Dixon, Ill., for "meritorious service and bravery, particularly in the 37th Division's campaign in Manila." Dr. Holladay graduated from Northwestern University Medical School, Chicago, in 1931 and entered the service March 15, 1941.

Major Samson D. Entin

Major Samson D. Entin, formerly of Chicago, was recently awarded the Bronze Star "for meritorious service with the 65th Infantry Division in France, Germany and Austria for the period March 5 to May 8, 1945." Dr. Entin graduated from Loyola University School of Medicine, Chicago, in 1936 and entered the service March 5, 1941.

Captain Martin M. May

Capt. Martin M. May, formerly of Marion, Ill., was recently awarded the Bronze Star and the Meritorious Service Unit Plaque. Dr. May graduated from St. Louis University School of Medicine in 1938 and entered the service Oct. 7, 1942.

MISCELLANEOUS

DIRECTORY OF APPROVED SURGICAL TRAINING PLANS

The American College of Surgeons recently published a 424 page directory in which are listed and described the approved programs of graduate training in surgery in 240 civilian hospitals in the United States and Canada and in 32 Naval, 7 Veterans Administration and 10 United States Public Health Service hospitals. The directory is chiefly an aid to medical officers returning from war duty and was made possible through the financial aid of a number of industrial organizations which have made contributions as a tribute to medical officers in the governmental services during the war.

UNRRA NEWS

Report on Work Done in Greece

Miss Rosamond Wansborough, an English nurse with special training in dietetics, recently returned from Greece after ten months of service as a nurse and dietitian in the mountainous areas of that country. In her report she states that only the UNRRA emergency food supplies saved thousands of lives and are giving the stricken villagers the heart to prepare for the coming winter. Last spring most people in these villages were scarcely strong enough to carry their own food from the warehouse to their homes. Many still suffer from apathy and depression as a result of prolonged starvation. UNRRA's food program is designed to bring the basic ration up to 2,000 calories a day for each person. Included for children are special rations of cod liver oil, powdered milk and soup. Infant mortality is now dropping, and children are beginning to resume normal growth.

Communicable Diseases in Europe

The principal communicable diseases threatening the present health of Europe, according to a summary of the epidemic situation on that continent made public recently by UNRRA in Epidemiological Information Bulletin No. 17, are typhus in the east, typhoid in both west and east and malaria in the Mediterranean area. Tuberculosis, diphtheria and syphilis are generally prevalent. Dysentery has been reported on the increase in a number of areas including Great Britain, and outbreaks of poliomyelitis have been noted in Belgium and Czechoslovakia.

Systematic control measures, especially the use of DDT to kill lice, have all but succeeded in eradicating epidemic typhus west of the Elbe-Adriatic line. In the eastern part of Europe the forced movements and resettlements of population now in progress are aggravating all problems of disease control. Malaria control too has been simplified by the use of DDT, but typhoid and dysentery will be harder to curtail.

The bulletin also advocates control measures to stop the spread of tuberculosis but is aware that this problem is tied up with "the slow nursing back to health of a war-torn continent." The issue also contains a survey of infant mortality in large towns and reports on the prevalence of plague, cholera, yellow fever, smallpox, relapsing fever and other communicable diseases throughout the world.

Diphtheria—Still Leading Epidemic Disease

Diphtheria, which reached epidemic proportions in a large part of central and northern Europe in 1942 and 1943, continues to be the leading epidemic disease and is still increasing rapidly in both Finland and Germany. In the Netherlands diphtheria has become one of the chief causes of death, as far as infectious diseases are concerned, second only to tuberculosis. France, Czechoslovakia, Belgium and Austria continue to have high morbidity and mortality rates from diphtheria. Only in Norway has the diphtheria wave reached its peak and begun to subside. The United Kingdom and Hungary have been able to continue methods of immunization in use prior to the war and have a comparatively low number of diphtheria cases.

That the epidemic is not confined to the Western World is proved by reports of Japanese civilian officials to the Pacific Office of the Chief Surgeon, U. S. Army, which show that diphtheria is the most important epidemic disease in Japan. The Philippines also have a large number of cases.

Three Tons of DDT Released for Italy

Following an outbreak of bubonic plague at Taranto, Italy, where 23 cases were reported, UNRRA is dispatching by air from London two sanitation experts and a cargo of rat extermination materials in response to an appeal from Italian health authorities. All of the reported cases, 11 of which were fatal, were traced to a warehouse on the water-front of the Italian naval base.

UNRRA immediately released 3 tons of DDT for dusting the population of the area and killing the fleas which carry infection from rats to man. A truck to haul the equipment used for cyaniding ships in the port to kill the rats was also made available. The British Ministry of Food has lent McAuley Gracie, one of the two disinfestation experts reporting at Taranto, who will train Italian health officers in rat extermination. As a precaution against a further outbreak, plague vaccine to immunize 100,000 individuals is being sent from UNRRA's European office in England.

PHYSICIANS SEPARATED FROM SERVICE

ARMY MEDICAL CORPS OFFICERS RECOMMENDED FOR/OR RELIEVED FROM ACTIVE DUTY

Alabama

Ford, Henry G., Lt. Col., American National Bank, Gadsden.
Gelperin, Jules, Capt., 3809 12th Court South, Birmingham.
Glazer, Harry, Capt., 219 S. Hull St., Montgomery.
Moorman, John D., Major, 214 W. Holmes St., Huntsville.
Nethery, Sidney J. Jr., Major, Belle Mina.
Newburn, George W., Jr., Capt., T. C. I. Hosp., Fairfield.
Shelamer, Arthur M., Major, 202 N. Madison, Athens.
Thigpen, Francis M., Capt., 401 S. Court, Montgomery.

Arkansas

Kemp, Karlton H., Capt., 1124 Hickory St., Texarkana.
Maguire, Frank C., Capt., County Health Unit, Blytheville.

California

Ahlering, Joseph Jerome, 1st Lt., General Hospital, Frensno.
Cappeller, Wm. S., Capt., 789 Buena Vista Ave., San Francisco.
Comroe, Jules B., Major, 1050 Franklin St., San Francisco.
Custer, Lawrence R., Col., 909 Hyde St., San Francisco.
Garretson, Kirk D., Capt., 4119 Manila Ave., Oakland.
Gibbs, Gordon E., Capt., Thermal.
Haakinson, William H., 1st Lt., 1750 Park Ave., San Jose.
Jones, Floyd H., Major, 2603 E. Broadway, Long Beach.
Jones, Theodore C., Capt., 511 E. Manchester Blvd., Inglewood.
Joseph, Peter S., Capt., 1200 Washington St., San Francisco.
Koerper, Victor E., Capt., 3850 Montecito, Santa Rosa.
Leichter, Martin, Capt., 839 N. Poinsetta Pl., Los Angeles.
Loy, Monroe F., Major, 312 N. Boyle Ave., Los Angeles.
Miller, Albert G., Capt., 205 3d Ave., San Mateo.
Moulton, Rowland R., Major, 1032 LaCuesta, San Mateo.
O'Grady, W. E., Capt., 555 Buena Vista Ave., San Francisco.
Porter, Marshall E., Capt., Mendocino State Hosp., Talmage.
Powell, Forrest G., Capt., 620 W. Grove St., Visalia.
Spencer, John A., Capt., 1970 16th Ave., San Francisco.
Stark, Morris, Capt., 2416 Holly Ridge Dr., Hollywood.
Stewart, Harry B., Capt., 525 Nyrtle Ave., Modesto.
Yee, Jacob J., Lt. Col., 1531 W. St., Sacramento.

Colorado

Evans, Russell J., Lt. Col., 326 Colorado Blvd., Denver.
Krausnick, Keith F., Major, Yuma.
Lewin, Julian R., Major, 1282 St. Paul St., Denver.

Connecticut

Cotton, John M., Lt. Col., 200 Retreat Ave., Hartford.
Detora, Albert M., Capt., 657 High St., Middletown.
Hersey, Thomas F., Capt., 44 Park Ave., Hamden.
Krinsky, Charles, Capt., 951 Ocean Ave., New London.
Stankard, William F., Capt., 14 Cold Spring Rd., Stamford.
Voris, Jacques V., Capt., 132½ Main St., Norwalk.

Delaware

Ackart, Richard Jenks, Capt., "Rockmere," Wilmington.
Johnson, Wallace M., Major, 257 Main St., Newark.

District of Columbia

Finnegan, John F., Capt., 1342 E. Capital St., Washington.
Grennan, Henry A., Lt. Col., 4000 Cathedral Ave., Washington.
Kauffman, Julius, Capt., 818 Gallatin St., N.W., Washington.
Tumulty, Philip A., Capt., 4955 Glenbrook Rd., Washington.

Florida

Hanks, George W., Major, 5708 2nd Ave., N., St. Petersburg.
McKenzie, Jack A., Major, 701 Huntington Bldg., Miami.
Marks, Bert W., Capt., 1619 Jefferson Ave., Miami Beach.
Strumpf, I. J., Lt. Col., 1360 Morvenwood Rd., Jacksonville.

Georgia

Beard, Donald Edwin, Major, RFD No. 1, Smyrna.
Candler, Robert W., Lt. Col., 2498 Montview Dr., N.W. Atlanta.
Clements, Claude A., Capt., La Fayette.
Roper, C. James, Capt., Roper Hospital, Jasper.
Sherman, John H., Lt. Col., 2350 McDowell St., Augusta.
Stewart, Philip R., Major, 406 Walton St., Monroe.
Victor, Samuel, Capt., A. C. L. Hospital, Box 158, Waycross.

Illinois

Ablaza, Avelino Enriquez, Capt., 9054 S. Jefferson Ave., Chicago.
Ahern, Thomas Francis, Capt., 8223 Luella Ave., Chicago.
Brott, Everel W., Major, Lena.
Bunata, Emil J., Major, 1810 S. Clarence Ave., Berwyn.
Dunn, Marion F., Capt., Hinsdale Sanit., Hinsdale.

Illinois—Continued

Feinhandler, Harold S., Capt., 3156 W. Diversey Ave., Chicago.
Gunther, Aaron, Major, 3403 Lawrence Ave., Chicago.
Hamlin, Courtney N., Major, 1364 Brown Hills Rd., Rockford.
Jacobs, Henry J., Major, 218 E. Minn St., Spring Valley.
Jacobson, Herman A., Col., 2641 Carmen Ave., Chicago.
Malbin, Barney, Major, 5527 S. Dorchester Ave., Chicago.
Martin, John, Major, 303 E., Superior St., Chicago.
Meagher, George B., Capt., DePue.
Pallasch, Gervaise P., 1st Lt., 3016 Logan Blvd., Chicago.
Parker, Francis W. Jr., 1st Lt., 303 E. Superior St., Chicago.
Pellettieri, Nino M., Capt., 5137 W. Crystal St., Chicago.
Restivo, Jack L., Capt., 3058 W. Harrison, Chicago.
Richards, Francis L., Capt., Price Sanitarium Bldg., Springfield.
Rosenberg, Nathan, 1st Lt., 656 Wrightwood Ave., Chicago.
Schiff, Charles A., Capt., Michael Reese Hospital, Chicago.
Sinow, Sidney A., Capt., 302 E. South St., Clinton.
Stein, Philip J., Lt. Col., 7300 S. Shore Dr., Chicago.
Wolff, Luther H., 1st Lt., 215 N. Sheridan Rd., Waukegan.

Indiana

Abell, Charles Frederick, Capt., 420 W. 4th St., Marion.
Bailey, Edwin Blackwell, Capt., 560 A. St., N.E. Linton.
Boling, R. L., Capt., 4450 Marcy Lane, Apt. 120, Indianapolis.
Chambers, Leroy B., Capt., 800 N. Columbia St., Union City.
Cook, Charles E., Capt., 112 N. Market St., North Manchester.
Davidson, Wm. D., Major, 3115 E. Blackford Ave., Evansville.
Durkee, Mervin, Lt. Col., 102 E. Virginia St., Evansville.
Fisher, John E., 1st Lt., Clarksburg.
Hill, Kenneth G., Major, 201 E. 33rd St., Indianapolis.
Johnson, Robert B., Major, Muscatatuck Colony, Butlerville.
Kwitny, I. J., Lt. Col., 2829 N. Pennsylvania Ave., Indianapolis.
McElroy, Robert S., Major, 704 W. State St., Princeton.
Manley, Charles N., Major, Rising Sun.
Miller, Carl G., Major, 457 Oakdale, Ft. Wayne.
Nugen, Harold, Capt., 326 W. 7th St., Auburn.
Rossman, W. B., Capt., 1801 N. Kessler Blvd., Indianapolis.
Shuler, Lacey L., Major, 5868 Washington Blvd., Indianapolis.
Smith, William B., Major, 1125 Bradbury Ave., Indianapolis.
Steele, Dick J., Capt., 207 Northwood Blvd., Greencastle.
Wallace, H. C., Lt. Col., 107 W. Jefferson St., Crawfordsville.

Iowa

James, David W., Major, Kamrar.
Kiesau, Kenneth R., Capt., 208 Rossville Rd., Waukon.
Lister, Kenneth E., Major, Yocum Hospital, Chariton.
Missildine, Whitney H., Major, University Hospital, Iowa City.
Nachtwey, Robert A., Major, Lansing.
Niemann, Theodore V., Capt., Brooklyn.
Taylor, Wendel W., Major, Ireton
Wall, David, Capt., 416 Franklin St., Ames.
Wolpert, Paul L., Capt., Onawa.
Wray, Robert M., Major, 402 25th St., S.E., Cedar Rapids.

Kansas

Polson, Robert C., Capt., 1129 Louisiana, Lawrence.
Jordan, Ralph E., Major, 503 Campbell, Beloit.
Melchert, Harold B., Major, 24 S. Mission, Council Grove.
Weinberg, Bernhard J., Capt., 1302 W. 4th Blvd, Coffeyville.
Wolohon, Harry C., Capt., Scammon.

Kentucky

Burks, James M., Capt., Leithfield.
Carr, Arch M., Capt, Alva.
Coe, George R., Capt., 118 Home, Erlanger.
Cohen, Robert, Major, 939 Eastern Pkwy. Louisville.
Foley, James D., Capt., Loyall.
Merlis, Jerome K., Capt., 101 W. Chestnut St, Louisville.
Schickel, Joseph, Capt., Burkesville.
Townsend, William M., Capt., Falmouth.
Wright, Thomas J., Capt., 1857 S. Limestone, Lexington.
York, Paul S., Major, Glasgow.

Maine

Brown, Freeman F. Jr., Capt., 5 Beech St., Rockland.
O'Sullivan, William B., Capt., 345 Maine St., Biddeford.

Mississippi

DeJarnette, Robert H., Capt., 1619 Filmore St., Corinth.
Hedmeg, Andrew, Major, 203 Gresham St., Indianola
Lunceford, William H., Capt., Slate Spring.
Ryan, Everett W., Lt. Col., Gulfport.

ORGANIZATION SECTION

"MEDICINE AND THE CHANGING ORDER"

Statement by the Committee on Medicine and the Changing Order of the New York Academy of Medicine in Comment on President Truman's Special Message to Congress on Nov. 19, 1945 Advocating Compulsory National Medical Insurance

During the past three years the New York Academy of Medicine, through its Committee on Medicine and the Changing Order, has been making an intensive study of current social and economic changes and of their effects on medical care and public health. This committee was appointed to study all problems involved in the distribution of adequate medical care, embracing not only the immediate management of the sick but also preventive medicine, public health, medical education and research, nursing, hospitals, convalescent care and rehabilitation, dental care, health education of the lay public, and finally the ways and means to meet the costs of such services. The Committee on Medicine and the Changing Order is not, in the strict sense of the term, a medical committee, nor does it represent solely the medical profession. It includes in its membership a large percentage of nonmedical persons, representing labor, industry, law, social work, the clergy and the public at large, who have had full opportunity to participate in the work of the committee and to express their points of view. The committee has met weekly and, at times, more often, to listen to the testimonies presented by invited experts. It has spent many hours in deliberation, collectively and in subcommittee meetings at which smaller groups of experts have studied and dealt with the specific phases of problems confronting present day medicine. The committee has been supported in its work by a corps of experts, and the costs of its work have been met by grants from the Commonwealth Fund, the Milbank Memorial Fund and the Josiah Macy Jr. Foundation. In every respect, therefore, the committee is representative of all varied and broad interests that are concerned in the problems of the extension and improvement of medical service.

The Committee on Medicine and the Changing Order has not yet completely formulated the recommendations of its final report, which it expects will be published during the current year. However, the special message sent to the Congress by President Truman on Nov. 19, 1945, in which he urges the creation of a system of national compulsory medical insurance as well as other changes in the organization of medical care in the United States, impels the New York Academy of Medicine, through its Committee on Medicine and the Changing Order, to issue a statement at this time.

The New York Academy of Medicine is essentially in accord with the objectives reflected in the President's message. It is fully cognizant of the many lacks in medical care which now exist in the United States and which most certainly are in need of urgent remedy. It agrees that the health of the people is a matter of national concern and that every effort should be made to provide all our people with adequate medical care and the opportunity to achieve and enjoy good health. However, while endorsing President Truman's objectives, the Academy cannot endorse all of the methods he proposes for their attainment.

We are mindful of the great achievements of modern medicine, which have been effected, particularly during the last forty years, under the prevailing system of medical practice. By the side of the many admitted inequities in the distribution of medical care stands the attested fact that the health record of the United States, as witnessed by mortality and morbidity statistics, is today outstanding. No nation of comparable size and complexity, with as many varieties of circumstances under which its people live and work, has attained as much in fostering the health of its citizens as has the United States. Before, therefore, venturing on untested schemes which involve abrupt nationwide changes we must strive to determine whether we could not achieve the objectives which the President has voiced and which we share more quickly and more effectively by procedures that are, in our opinion, less hazardous.

The President's message advances five specific recommendations. With the first of these, advocating the construction of hospitals and related facilities, the Committee on Medicine and the Changing Order is substantially in accord. In many rural areas and even in suburbs of large cities there is a serious shortage of hospital and clinical facilities. This problem, however, will not be solved by the simple procedure of erecting structures and creating physical facilities; for, to be effective, hospitals and health centers must be adequately staffed with competent personnel. At the present time there is not available, and the immediate future does not promise to provide, a large enough body of trained and experienced medical and other personnel to warrant a rapid expansion of hospital facilities. We are currently confronted with the distressing example of the grossly inferior hospitalization and medical care provided for our veterans. As in every other effort to extend and improve medical facilities, we are compelled to recognize the numerous interrelated factors—physical facilities, economic resources, medical education and training, and public education—each of which has a profound bearing on the other, and all of which, collectively, are essential to the expansion and improvement of the medical services.

The President's second recommendation proposes an expansion of public health, maternal and child health services. This too the committee endorses in principle, with the caution, however, that experimentation is needed to avoid the sacrifice of valuable facilities and procedures which are already functioning. We are not here venturing into virgin territory. Public health, as well as maternal and child health, has been the concern of the American public and of American government for many decades, and particularly during the last forty years. We already have many excellent facilities, some run by state and local official organizations, others by voluntary and professional groups. Whatever expansions are undertaken should be developed in relation to these existing facilities.

The President's third proposal, to advance and support medical education and research, the Committee on Medicine and the Changing Order also endorses in principle. Here too, however, governmental aid to medical education and research should be of such character that it fosters and supports but does not direct and dominate. The Academy, through its Committee on Public Health Relations, has already taken its stand on these matters in a resolution endorsing, with some slight modification, the Magnuson bill now before the Congress.

The President's fifth recommendation, that means should be devised for protecting workers against loss of wages resulting from sickness and disability, the committee endorses without reservation.

There remains to be considered the fourth of the President's recommendations, namely national compulsory medical insurance, labeled in the official address as "prepayment of medical costs." To this recommendation the Academy is definitely opposed. As a result of the studies of its Committee on Medicine and the Changing Order, the Academy is convinced that any scheme of national compulsory medical insurance at this time would lead to most unfortunate results affecting the health of the public and the science as well as the practice of medicine.

It is not possible, under the circumstances, to discuss this fourth proposal in the President's message in any detail. The proposed scheme of prepayment of medical costs based on the enactment of compelling legislation and the collection of tax moneys is deceptive in its simplicity. Our studies have shown that the problem of providing for extensions of medical care is far from simple; indeed it is extremely complex, for it involves not only readjustments in the care of the sick but also, among other factors, the structure and content of medical education and the broad fields of social, industrial and preventive medicine. Payment for medical care through insurance represents only a fragment of the problem. It should be obvious that insurance cannot do more than spread a portion of the risk of costs. It cannot solve our medical problems because it cannot create the services essential for improving and extending medical care. It will not of itself teach the public to appreciate or to utilize effectively whatever medical resources are even now available to it. Insurance is most certainly incompetent to raise the quality of medical practice.

On the contrary, there is a wealth of experience which shows that under compulsory medical insurance on a nationwide scale though a larger number of people receive medical care, the quality of medical service rendered by the individual physician tends to decline.

Under our present forms of rendering medical care, which the President indicates would remain unchanged, the direct payment for medical services by a third party, the insurance fund, introduces a fundamental disturbance in the attitudes of both the subscribers and the doctors. The patient is tempted to demand more attention than he requires. Still more serious is the temptation of the practitioner to add to his income by rendering unnecessary service. Excessive demand, on the one hand, and unnecessary service, on the other, inevitably result in superficial performance. The financial rewards for volume of service and the pressure of patients constitute a combination of influences which to many is irresistible. This has been the recent experience in New Zealand, and it has been our own experience in the operation of workmen's compensation insurance.

Unfortunately, the alternative method of payment under an insurance scheme, namely capitation, whereby an annual stipend is paid to the physician for each insured patient on his list, likewise produces objectionable results. When the financial reward is fixed, some physicians are tempted to render as little service as possible.

Experiences abroad and in the United States by no means preclude the success of carefully organized prepayment medical insurance plans in this country. At the present time, however, we in the United States do not know how best to develop such medical insurance. We need a good deal of carefully planned and regulated experimentation. We lack experience not only from the actuarial angle but, what is still more important, from the service angle. We must realize also that we have no basis in our own experience on which to estimate what the contemplated extensions in medical service are likely to cost. We do know from European experiences that, under national compulsory medical insurance, even as the general level of medical practice is lowered its costs are raised. Furthermore, in the light of our own political history we must recognize that wherever there are available for distribution large sums of "government money" there also thrive political influence and political patronage.

The Academy's Committee on Medicine and the Changing Order is not concerned with maintaining the "status quo" in medicine. It has devoted several years to exploring new methods for correcting the many deficiencies in medical service. As a result of its studies it is convinced that the problems involved in the improvement and extension of medical service to all the people of the United States are numerous and diverse; hence, the ways to their possible solution are, and must be, of many kinds. In the opinion of the committee the expansion of medical services indicated in President Truman's first, second and third recommendations, with the modifications noted, would serve immediately to extend and to improve the quality of medical care rendered to our people and to lay the foundation on which a better organization of the medical profession could be achieved.

In opposing the fourth recommendation, calling for immediate nationwide compulsory medical insurance, the committee maintains that the problem of payment can be solved by methods less menacing to the high standards of medical service which have developed in this country over the years. To this end it offers a series of interrelated proposals designed not only to make more medical service available to our people but also to improve its quality. These proposals are not easily summarized out of their context in the final report, but it is possible at least to indicate the diverse paths on which the committee believes we must travel if we are to reach an orderly solution of the many problems which today confront us.

The committee recommends, among other things, that voluntary, nonprofit insurance be given a thorough trial as a means of providing medical services for low income families. At the same time it recognizes that plans of this nature cannot be expected to solve the entire problem and that in certain instances, for example when private resources are inadequate, government support, preferably in the form of federal or state grants-in-aid, will be required. The committee holds further that it may be desirable to conduct careful experiments at state and local levels with compulsory government insurance, so that we may have in the near future comparative experience with the relative values of voluntary and compulsory procedure.

In order to raise the quality and to round out the scope of medical care extended under any system of payment, the committee favors not only a number of revisions in medical education but the gradual extension of group practice. Under this form of practice, which promises far reaching improvements in the organization of practitioners and specialists, doctors conduct a joint enterprise in medical care in close cooperation with high grade hospitals, sharing a common plan of remuneration and responsibility for the quality of service they render. The group system is especially attractive to young physicians entering the practice of medicine who have been accustomed to work together while in training as hospital residents and who desire to retain their relationship to the hospital, with all its educational and professional advantages. Even those physicians who settle in rural communities should eventually be able, under a well planned system of medical care, to retain or establish such a relationship to a medical center.

It is essential, moreover, that medical group practice units be organized also in relation to teaching hospitals, since an extension of prepaid medical care to all people of low income must inevitably have important repercussions on medical education and research. The medical schools, for their part, must change their methods if they are to train doctors for a new form of medical care; and no form of medical care can afford to neglect the advantages to the patient of teaching and research.

Because it is much more economical—not alone in terms of money but in human values—to prevent the occurrence of illness than to cure it, the committee places special emphasis on preventive medicine in all forms of practice. To the same end, immediate efforts should be made to provide basic public health services for communities which are now lacking in those services. The committee insists also that further education and enlightenment are sorely needed by all groups concerned—by government agencies, by the medical professions, by private welfare organizations and, most of all, by the public at large.

What is wanted at this time, therefore, is not an overall national compulsory scheme but a variety of studies and experiments conducted by smaller units at local levels. Specific recommendations as to how such pilot studies and experiments may be carried out will be contained in the final report of the committee.

It is the conviction of the Academy that an evolutionary transformation of medical practice is essential if the benefits of modern medicine, and especially of preventive medical services, are to be made more freely available to the people. It is far better to proceed in a somewhat slower but more orderly manner than to expose the nation to the risks, as yet unmeasurable, which immediate adoption of national compulsory medical insurance would entail.

Washington Letter

(From a Special Correspondent)

Jan. 7, 1946.

New Virus Disease with 40 per Cent Death Rate

Results of work by the National Institute of Health have been reported by Drs. B. J. Olsen and C. L. Larson of the U. S. Public Health Service on a new virus disease with a 40 per cent death rate reported to have entered the United States. The virus is said to belong in the same general classification as psittacosis, but it spreads directly from one person to another. The malady has pneumonia-like symptoms, and when it first appeared it was confused with the virus type of this disease. The virus was isolated at laboratories of the Louisiana State Health Board and the National Institute of Health. Its only recorded appearance was in Louisiana two years ago and it proved fatal in 8 of 19 cases. The virus was obtained in almost pure form at the Washington laboratories and a technic was developed for producing it in chick embryos. It quickly killed rats, mice and guinea pigs but had no effect on muskrats or ferrets. The virus would not respond to the sulfonamide drugs or to penicillin.

Veterans' Need for Hospital Highlights National Shortage

The appeal by the Veterans Administration to army, navy and civilian hospitals for the temporary loan of 40,000 beds to care for veterans has prompted newspapers to interpret the request as an indication of a critical national hospital shortage. The Veterans Administration reveals that its hospitals have beds for slightly more than 70,000 patients but that 150,000 beds will be needed by 1950 for members of the armed forces. The Navy has undertaken to supply 10,000 beds by September and the Army has been requested to furnish a similar number. Civilian hospitals are already overcrowded, and it has been proposed that a survey of civilian hospital facilities would be useful.

Medical Society Organized to Meet Cold Epidemic

Of general interest is the way in which the District of Columbia medical societies organized to provide medical care for families without a family doctor during the epidemic of colds. Dr. Walter R. Stokes, chairman of the society's committee on public relations, said "We recognize that many persons are having difficulty locating physicians to make home calls. We would suggest to them, if they do not have their own physicians, that they call the Medical Bureau, which will put them in touch with a doctor. Many doctors recently returned from the military service are listed with the bureau." Secretary Theodore Wiprud said about two hundred physicians are listed to accept emergency calls.

National Research Council Fellowships Resumed

Applications must be in by February 1 for special fellowships established by the National Research Council to enable young scientists whose graduate studies were interrupted by the war to resume their work toward the doctorate. The fellowships were made possible by a grant of $335,000 from the Rockefeller Foundation to help fill up the war-created gaps in research workers' ranks with the least loss of time. Successful applicants will be given $1,200 a year for single persons and $1,800 for married men, with an additional allowance up to $500 a year for tuition fees.

Allocation Controls Restored on Penicillin January 1

A sharp increase in demand for penicillin prompted the Civilian Production Administration to restore allocation controls over the drug, effective January 1. Prevalent illness throughout the country is blamed for the heavy current demand. Allocation of penicillin is expected to insure sufficient supplies for requirements of the Army, Navy, Veterans Administration, the Public Health Service and other domestic consumers.

Trial of Artificial Limb Makers Set for March 11

A Federal District court has set March 11 for the trial of a trade association, forty-five corporations and thirty-four individuals charged with violations of the Sherman Anti-Trust Act in the manufacture and sale of artificial limbs.

Lemke Presses for Bill Against Experiments on Animals

"Immediate action" will be sought by Representative Lemke, Republican of North Dakota, on his bill to end animal experimentation in Washington, when Congress comes back from its vacation. He says he will ask Representative McMillan, Democrat of South Carolina, chairman-elect of the House District Committee, for an early hearing. The Lemke bill provides a fine of $500 and imprisonment up to one year or both for any surgical operation performed in the District of Columbia on a dog other than for strictly curative purposes. The bill was introduced a year ago January 3 but has been dormant before the committee. Senator Langer, Republican of North Dakota, says he will give the bill full support when it reaches the Senate.

Veterans Administration to Give Veterans Preference

War veteran doctors will get preference in hiring by the Veterans Administration, Gen. Omar Bradley, administrator, assured after President Truman signed the controversial measure creating a separate medical department in the agency. Full page advertisements are being published to acquaint the profession with new opportunities at good salaries in the agency for medical men. The bill assures a complete new deal in medical care for veterans. It was approved against strong opposition of the Civil Service Commission. Major Gen. Paul R. Hawley, Acting Surgeon General, will continue temporarily as chief of the medical service, which will be put into effect immediately.

Tuberculosis the Principal Health Scourge in Greece

John Dula, senior child welfare specialist of the United Nations Relief and Rehabilitation Administration, reports that tuberculosis is the most virulent scourge in Greece today, with malaria a runner up. He saw entire villages in which every citizen seemed to be suffering from tuberculosis. Although there is less starvation, disease is widespread because many persons are still crowded together in dugouts, basements and lean-tos. Through joint efforts of the UNRRA, the Greek War Relief Association and the Greek government, vitamin foods are being served daily to thousands of child war victims.

Use of Atom for Health and Industry

The theory and production of atomic energy and the use of fissionable materials for health and industry would be studied by an atomic energy commission proposed in a bill introduced in Congress by Senator Brien McMahon, Democrat of Connecticut. The commission would have broad powers over the entire field of atomic science. Sixty days after passage of the proposed act it would be unlawful for any person to own or export fissionable materials. Senator McMahon is chairman of the special Senate Committee on Atomic Energy.

General Kirk and Mrs. Truman Launch Nurse Memorial Campaign

The campaign to raise $2,000,000 for a Nurse's National Memorial in Washington was opened here with Major Gen. Norman T. Kirk, Surgeon General of the Army, as principal speaker, and Mrs. Harry S. Truman guest of honor. After the luncheon Mrs. Dwight D. Eisenhower and wives of other high ranking army and navy officers who are sponsors signed certificates for those making contributions.

Duplication of Health Services in the Government

In an article revealing duplication in federal government agencies, Lindsay C. Warren, U. S. Comptroller General, points out that all public welfare activities are supposed to have been coordinated by the Federal Security agency. However there are still some half dozen agencies working on nutrition programs and research. These were two of many examples of waste cited by Mr. Warren.

Lehman Says UNRRA Needs More Funds

Herbert H. Lehman, director general of the United Nations Relief and Rehabilitation Administration, said that despite a new congressional authorization of $1,350,000,000 for 1946 the agency will have only sufficient funds to meet the most critical needs of devastated nations. With its current funds UNRRA must neglect many areas where help is needed.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

ARKANSAS

District Meeting.—The Ninth Councilor District Medical Society was addressed at Harrison December 14 by Drs. Charles T. Chamberlain, Fort Smith, on "Heart and Aviation," and by Frederick H. Krock, Fort Smith, on "Medical Practice in the South Pacific."

CALIFORNIA

Industrial Hygiene Change.—Dr. Douglas G. MacPherson, San Francisco, formerly director of the Los Angeles City Division of Industrial Hygiene, is now chief of the Los Angeles County Division of Industrial Hygiene. He replaces Dr. Hugh E. Dierker Jr., who has become medical director of the Southern California division of General Motors Corporation, according to the *Industrial Hygiene News Letter.*

Lawrence Kolb Accepts New Mental Position.—Dr. Lawrence Kolb, Washington, D. C., formerly chief of the mental hygiene division of the United States Public Health Service, has been appointed deputy medical director of the State Department of Mental Hygiene in California. The first of its kind in California, the post was created by the 1945 legislature on the recommendation of Mrs. Dora Shaw Heffner, director, according to *Modern Hospital.*

Lectures by Dr. Owen Wangensteen.—Dr. Owen H. Wangensteen, professor and head of the division of general surgery, University of Minnesota Medical School, Minneapolis, presented a lecture on December 14 before Alpha Omega Alpha at Stanford University School of Medicine, San Francisco, entitled "Intestinal Obstructions." On December 15 he presented a lecture before the California Academy of Medicine, San Francisco, entitled "The Ulcer Problem."

CONNECTICUT

James Hamilton Leaves New Haven Hospital.—James A. Hamilton, who has been director of the New Haven Hospital, New Haven, for seven years, has announced his retirement, effective January 1. Mr. Hamilton will join a group of other hospital administrators to establish a hospital consulting service. He will continue as lecturer in hospital administration at Yale University School of Medicine, New Haven, according to *Modern Hospital*

Survey of Tumor Clinics.—Dr. Nestor William Wawro, New Haven, has been chosen to conduct a study of the clinical aspects of the tumor clinics of Connecticut. The appointment was made by the committee on tumor study of the Connecticut State Medical Society, which is cooperating with the Association of Tumor Clinics. Dr. Wawro's studies will fit into the joint plan of the basic audit or survey sponsored by the Connecticut Cancer Society. The entire project was initiated to guarantee that the funds of the society would be spent wisely.

State Society Holds Dinner Meeting.—A feature of the semiannual meeting of the house of delegates of the Connecticut State Medical Society, New Haven, December 13, was a dinner session attended by the society of the woman's auxiliary. Among the speakers at the dinner were:

Dr. Joseph H. Howard, Bridgeport, president of the Connecticut State Medical Society.
Mrs. James Raglan Miller, Hartford, president, woman's auxiliary.
Dr. John F. Kenney, Pawtucket, president, Rhode Island Medical Society.
Dr. Roger I. Lee, Boston, president, American Medical Association, the title of whose address was Timeo Danaos et Dona Ferentes.
Dr. Morris Fishbein, Editor of The Journal, who spoke on Medicine in the Postwar World.

INDIANA

Cancer Society Organized.—The Indiana Cancer Society, Inc., has been created with William H. Ball, Muncie, as president and Mrs. A. L. Taggart, Indianapolis, secretary. The purpose of the organization is to collect and disseminate information concerning the symptoms, diagnosis, treatment and prevention of cancer and to aid, in cooperation with accredited physicians, in the establishment, development, equipment and maintenance of hospitals, clinics, laboratories and other facilities for the care of cancer patients and for research into the cause and cure of cancer.

IOWA

Personal.—Dr. Max L. Durfee, Cedar Falls, has resigned at the University of Oklahoma to return to his position as director of the student health center at the Iowa State Teachers College.——Dr. Melvin T. Johnson has been named medical director of Iowa Public Health District number 5, Fort Dodge, succeeding Dr. Forrest J. Austin, now of Omaha, resigned.——Robert E. Neff, Ph.D., Iowa City, has been appointed superintendent of the Methodist Hospital, Indianapolis.

KANSAS

Graduate Medical Education.—On January 21-25 a course on physical medicine and occupational therapy will be held at the University of Kansas School of Medicine, Lawrence-Kansas City, Mo. This is the second course in a series planned by the new division of graduate medical education, of which Dr. Edward H. Hashinger, professor of clinical medicine, is acting director. The first course was held October 29-November 2 on general therapeutics. Other courses in the series include:

Pediatrics, February 25-March 1.
Internal medicine, psychiatry and dermatology, March 25-29.
Eye, ear, nose and throat, April 15-19.
General surgery and radiology, May 13-17.
Obstetrics and gynecology, June 17-21.

MASSACHUSETTS

Refresher Course for Discharged Medical Officers.—Harvard Medical School will offer a six months refresher course, beginning February 1, to medical officers discharged from the armed forces. The course, under the supervision of Dr. Eugene C. Eppinger, Boston, assistant dean, formerly a colonel in the army, will emphasize current scientific knowledge and theories and advances in the medical field. Instruction will be given by the regular members of the preclinical and clinical departments of the medical school. In offering such a course the medical school is attempting to assist individuals who on separation from the service wish to obtain the latest knowledge in the broad field of medicine in preparation for reentering a civilian medical career. Dr. Eppinger was most recently chief of the communicable disease branch of the Medical Consultants Division, Office of the Surgeon General, in Washington, and is now returning to Harvard Medical School, Boston, as assistant dean in charge of courses for graduates.

MICHIGAN

Changes in Health Personnel.—Dr. Russell E. Pleune, Hancock, formerly director of the Houghton-Keweenau-Baraga Health Department and recently released from the army, has been appointed deputy commissioner of health of the upper peninsula with offices in Escanaba, with the state board of health. Dr. Pleune will succeed Dr. Wilber J. M. Menke.

Upjohn to Erect New Antibiotic Plant.—With the purchase of 500 acres 4 miles southeast of the city, the Upjohn Company, Kalamazoo, recently announced plans to expand its facilities for the manufacture of antibiotics. Streptomycin, as yet produced only in pilot laboratory quantities, will be put into large scale production when the new plant is finished. George F. Cartland, Ph.D., who has been head of the company's research work in antibiotics, will supervise the operation of the new unit under M. C. Hart, Sc.D., vice president and director of research.

MONTANA

Personal.—Dr. Carl W. Hammer, Oxford, Mich., has been named assistant professor of health education at the Montana State College, Bozeman, and director of the Student Health Clinic, it is reported.——Dr. Harry V. Gibson, health officer for a number of years of Great Falls, has been placed in charge of the reorganized health department in Great Falls and Cascade County.——Dr. Raymond L. Eck, Lewistown, has been named coroner of Fergus County.

NEW JERSEY

Hospital Overcrowded, Patients Cared For in Home.—With 691 patients crowding the Newark City Hospital, a plan for home treatment of the sick, beginning December 14, was announced in the *New York Times.* Patients will be treated by private physicians in their homes at rates of $2 a visit during the day and $3 at night. The municipality will pay the physician's fees on proof of the patient's indigence. Otherwise the patient will pay.

NEW YORK

Millions to Be Spent in Syracuse Expansion.—Syracuse University College of Medicine is planning an expansion program to cost between $20,000,000 and $25,000,000 in the next ten years, newspapers report. The program will include an expansion of the medical center, a new university hospital and a ten story addition to Memorial Hospital.

Personal.—Dr. Archibald S. Dean, district state health director, on November 19 was appointed acting head of the department of hygiene and public health, University of Buffalo School of Medicine, filling temporarily the position formerly held by Dr. William T. Clark, now superintendent of the Masonic Home and Infirmary, Utica.

Walter Pamphilon Named Assistant Commissioner of Mental Hygiene.—Dr. Walter M. Pamphilon, Willard, assistant director of the Willard State Hospital, has been named assistant commissioner of the New York State Department of Mental Hygiene. According to the *Psychiatric Quarterly*, Dr. Pamphilon, who had previously been detailed as acting medical inspector, has been assigned to the inspection service of the department and will be on duty in the New York City office for part of his time, besides assisting with the department's program for postwar building. Graduated at the University of Toronto Faculty of Medicine in 1922, Dr. Pamphilon entered the state service at Buffalo State Hospital in 1922. He had been at Willard since 1933, when he went there as first assistant physician, later being designated as assistant director. Dr. Kenneth K. Slaght, assistant director at Rochester State Hospital, has been named acting medical inspector.

New York City

The Harvey Lecture.—Max Delbruck, Ph.D., assistant professor of physics, Vanderbilt University, will deliver the fourth Harvey Lecture of the current series at the New York Academy of Medicine on January 17. Dr. Delbruck will speak on "Experiments with Bacteriophages."

Dr. Merrill Wins the Modern Hospital Award.—Dr. Ambrose P. Merrill Jr., superintendent of the Home for Incurables, is the winner of the 1945 Modern Hospital Gold Medal Award. His prize winning article, "Suspect Nurseries—A Case History of Experience at St. Luke's Hospital, Chicago," appeared in the *Modern Hospital* for January 1945, shortly after he moved to New York from St. Luke's Hospital, Chicago, where he served as medical director for three years. Honorable mention certificates were awarded to Dr. Edmund E. Walker, superintendent, Springfield Hospital, Springfield, Mass., and Jennie F. I. Dixon, director of social service at Springfield Hospital, for their article "Chronic Disease Ward," published in the June 1945 issue of the *Modern Hospital*.

Blood Bank for Cancer Patients.—The establishment of a field army blood bank for cancer patients at Memorial Hospital was announced December 11. Registration of donors will be handled at 2 West 106th Street, the Old Memorial Hospital Building, which is also Field Army headquarters. Blood donations by members of the Field Army who volunteer will be taken at the New Memorial Hospital, 444 East 68th Street. Blood of those acceptable will be used for cancer patients who are unable to pay a professional donor. If blood is given to a patient able to pay, the money received will be placed in the general fund of Memorial Hospital, where it will accrue to the benefit of cancer patients. The service will be extended to other hospitals as required.

Medical and Hospital Librarianship.—The School of Library Service of Columbia University announces for the 1946 summer session a program of related courses on medical and hospital librarianship. One course, medical library administration, aims to equip librarians to administer medical, nursing, pharmaceutical and dental libraries. Administrative matters, such as the cataloguing and classification of medical literature, personnel problems, budgets, the rare book room, reference service and the selection and purchase of books and periodicals, will be presented. Emphasis also is to be laid on the literature of medicine and its collateral sciences. A second course, library work with hospital patients, treats the values of library work with patients, the facts and conditions affecting its performance, the selecting of books and the managing of collections for use in it, and ways of dealing with ill people and meeting their needs. Brief attention is given to the conducting of libraries for the physicians and nurses of a hospital staff. Field assignments and visits of observation may be arranged for students desiring to supplement their study in this way. Some may like also to pursue certain related library school courses, notably psychologic foundations of reader guidance and reading interests and habits of adults, or several guidance and psychology courses given elsewhere on the campus. Further information may be obtained by addressing the Dean, School of Library Service, Columbia University, New York 27.

NORTH CAROLINA

Medical and Surgical Symposium.—The third annual medical and surgical symposium of the Watts Hospital, Durham, will be held February 13. Among the speakers will be:

Dr. Wilburt C. Davison, Durham, Some Remarks on Postgraduate Medicine.
Lieut. Col. Louis A. M. Kruse, Camp Butner, Some Hemolytic Processes Including the Rh Factor.
Dr. Norris W. Vaux, Philadelphia, The Treatment of Habitual Abortion.
Dr. Edward A. Strecker, Philadelphia, Psychiatry Speaks to Democracy—About Mothers and Moms.
Dr. Arthur M. Shipley, Baltimore, Diverticulitis of the Colon.
Dr. James E. Paullin, Atlanta, Ga., The Relationship of Medical Practice to Gerontology.
Dr. Louis Hamman, Baltimore, General Features of Periarteritis Nodosa, Particularly from the Standpoint of Diagnosis.
Dr. Isidor S. Ravdin, Philadelphia, The Pathologic Physiology of Biliary Tract Disease.
Dr. Eugene P. Pendergrass, Philadelphia, The Roentgenologic Aspects of Biliary Tract Disease.

In addition there will be clinical pathologic conferences conducted by the members of the staffs of the Medical College of Virginia, Richmond, and the University of Virginia Department of Medicine, Charlottesville.

NORTH DAKOTA

Changes in State Health Department.—Dr. William M. Smith, Rome, N. Y., from 1937 to 1942 assistant district state health officer in New York State and recently released from military service, has been appointed director of the division of preventable diseases of the North Dakota State Department of Health, Bismarck. Dr. George F. Campana, Albany, state health officer, has been acting health officer of the division. Dr. Robert R. Kling, Rochester, N. Y., has been chosen tuberculosis consultant in the division of preventable diseases.

OHIO

Health Officer for Twenty-Five Years.—Dr. Harley J. Powell, Bowling Green, health commissioner of Wood County for more than twenty-five years, was honored with a luncheon recently to mark the occasion and in recognition of his retirement, which was planned for the end of the year.

New Division Chiefs in State Departments of Health.—Dr. Percy L. Harris, Ravenna, health commissioner of Portage County since 1938, has been appointed chief of the division of communicable diseases of the Ohio State Department of Health, according to the state medical journal. Dr. Thomas F. Mancuso, acting director of the division in industrial hygiene, Oregon State Board of Health, Portland, has been appointed chief of the division of industrial hygiene of the Ohio Department of Health. Dr. Charles M. McGill, who has been serving in the Ohio position (THE JOURNAL, Oct. 20, 1945, p. 564), has taken over the Oregon activity.

Mental Hospital Dedicated.—Ohio's first receiving hospital for mental patients, the first of five such hospitals for which the state legislature made appropriations in the $23,000,000 expansion program of the state welfare department, was opened at Youngstown on November 20. The 85 bed hospital, which was the abandoned Youngstown Municipal Hospital, will serve fourteen northeastern Ohio counties. Others are to be located at Cleveland, Akron, Athens and Columbus. Dedication speeches were made by Frazier Raams, state welfare director, and Dr. Frank F. Tallman, Columbus, state commissioner of mental diseases, according to the *Ohio State Medical Journal*.

PENNSYLVANIA

Philadelphia

Survey of Tuberculosis Among the Diabetic.—The board of directors of the Philadelphia County Medical Society endorsed the proposed survey of the incidence of tuberculosis among diabetic patients to be conducted by the Philadelphia Tuberculosis and Health Association. The endorsement was influenced by favorable recommendations by the society's committees on diabetes and tuberculosis.

Course for Medical Laboratory Technicians.—The Jewish Hospital offers a twelve months training course for medical laboratory technicians and prepares young women for the examination given by the Registry of Medical Technologists of the American Society of Clinical Pathologists. Students are accepted who have had two years of college work with suitable college courses in chemistry, biology and physics. The course includes practical and theoretical training in bacteriology, serology, hematology, clinical microscopy, histology, parasitology and biochemistry. Prospective students should file a copy of their college credits with the director of laboratories and with the Registry of Medical Technologists, Ball Memorial Hospital, Muncie, Ind. Dr. Charles Weiss is the director of laboratories.

Pittsburgh

Special Society Election.—Dr. James A. Mansmann is the new president of the Pittsburgh Allergy Society; Dr. Lester L. Bartlett is secretary-treasurer.

Psychiatrist Recommended as Adjunct to Behavior Clinic.—Establishment of a psychiatric clinic as an adjunct to the behavior clinic in combating crime was proposed in the annual report of Dr. Edward E. Mayer, supervising director of the clinic, to the Allegheny County common pleas judges. Recalling that the behavior clinic provides the court with psychologic interpretations of prisoners, Dr. Mayer said that maladjusted prisoners with deep seated personality problems "should have the opportunity to be referred to a psychiatric clinic treatment." He further stated that such a clinic dealing with "the entire family situation would provide help for the excessive drinker, assist in reconciling couples seeking divorce and assist in adjusting the sexual psychopathic."

RHODE ISLAND

Cancer Detection Clinic.—A cancer detection clinic for women has been opened at the Rhode Island Hospital, Providence. The clinic is intended for semiannual physical examinations of well persons. It is free and will be open to any woman who wishes to attend. If any disease condition is found, the patient will be referred back to her own doctor or to one of a group of men who will be designated by the Rhode Island Medical Society.

TENNESSEE

New Professor of Anatomy.—Frank Harrison, Ph.D., assistant professor of anatomy, University of Tennessee College of Medicine, Memphis, has been appointed professor and head of the department of anatomy, effective April 1. Dr. Harrison succeeds Dr. Kendall B. Corbin, Memphis, who is to join the staff of the Mayo Clinic, it is reported.

Changes in Health Personnel.—Dr. Roy J. Settle, recently discharged from the army medical corps, has been appointed director of the Williamson County Health Department, succeeding Dr. William B. Farris, who went to Gallatin. Dr. Willoughby J. Rothrock Jr., Philadelphia, has been assigned by the U. S. Public Health Service as director of the tuberculosis control program for the Chattanooga-Hamilton County Health Department. Dr. Marion G. Fisher, Washington, has resigned as director of the Washington County Health Department, it is reported.

Sentence Two to Fifteen Years for Kidnaping Physician.—Two youths, both of Dayton, one 18 years of age and one 21, pleaded guilty in criminal court October 31 to charges of kidnaping and robbing Dr. German P. Haymore, Chattanooga, and were sentenced to serve fifteen years in the state penitentiary. According to the Chattanooga *Times* Judge Frank S. Darwin imposed a sentence of ten years each on the charge of kidnaping and added a prison term of fifteen years each in the robbery cases, the sentences to run concurrently. The physician was kidnaped early in August while sitting in his automobile.

UTAH

Regional Meeting for Clinic Research.—The first regional meeting of the Western Section of the American Federation for Clinical Research was held under the auspices of the University of Utah School of Medicine, Salt Lake City, at the Salt Lake County General Hospital, Salt Lake City, December 28-29. Among the speakers were:

Dr. Paul M. Aggeler, San Francisco, Platelet Counts and Platelet Function.
Dr. Louis S. Goodman, Salt Lake City, Experimental Determination of Anticonvulsant Activity.
Dr. Franz R. Goetzl, Oakland, Calif., The Influence of Acetylsalicylic Acid on Analgesic Effects of Induced Pain.
Dr. Carl G. Heller, Portland, Ore., Alarm Reaction in Burned Patients.
Dr. Abe Ravin, Denver, Congo Red in Myasthenia Gravis.
Dr. Ferdinand R. Schemm, Great Falls, Mont., The Effect of High Fluid Intake on Venous Pressure.
Dr. Maxwell M. Wintrobe, Salt Lake City, Studies on the Mechanism of Anemias of Infection.
Dr. Irving S. Wright, New York, Experiences with Dicumarol in the Treatment of Coronary Thrombosis.

WASHINGTON

Personal.—Dr. Clifford S. Halvorsen has been named superintendent of the Northern State Hospital, Sedro Woolley, effective December 1. Since Dr. Halvorsen returned from overseas, he has been chief of the neuropsychiatric service at Madigan General Hospital at Fort Lewis. Dr. Halvorsen succeeds Dr. James W. Doughty, Sedro Woolley, resigned, who held the position for twenty-nine years.

Appointments to State Board of Health.—Mr. Irvin R. Vaughn, who was appointed as acting state registrar with the state department on November 26, will be the acting head of the public health statistics section. Mr. Vaughn was formerly director of public health education and assistant director of vital statistics for the state board of health of South Dakota. Dr. Clarence Arthur Elden was appointed obstetric consultant with the state department of health on November 15 and will work in the maternal and child health and crippled children's section. Dr. Elden had previously been for thirteen years assistant professor of obstetrics and gynecology at the University of Rochester School of Medicine and Dentistry, Rochester, N. Y., and also was in private practice during that time.

WEST VIRGINIA

Mental Clinics.—Beginning January 1, semimonthly clinics will be conducted at Spencer State Hospital (mental) by Dr. Edward F. Reaser, Huntington, assistant superintendent at Huntington State Hospital, and Dr. Orin R. Yost, newly appointed superintendent at Weston State Hospital (The Journal, Dec. 8, 1945, p. 1037). This is part of a new program agreed on by Dr. Reaser, Dr. Yost and Dr. Charles T. Taylor, superintendent of the Huntington institution, and Alfred L. Morris, Jodie, head of the Spencer State Hospital, for the treatment of patients at the three state mental institutions.

GENERAL

New Journal of Medicine and Allied Sciences.—The first number of the new *Journal of the History of Medicine and Allied Sciences,* to be published quarterly by Henry Schuman, was to make its appearance in January. Dr. George Rosen is the editor.

Southeastern Surgical Congress.—The Southeastern Surgical Congress will hold its next assembly at the Peabody Hotel, Memphis, March 11-13. Additional information may be obtained from Dr. Benjamin T. Beasley, secretary-manager, Southeastern Surgical Congress, Atlanta 3, Ga.

Orthopsychiatric Meeting.—The American Orthopsychiatric Association will hold its annual scientific meeting at the Hotel New Yorker, New York, February 14-16. Recently The Journal, in a list of continuation courses, noted that this meeting would carry a registration fee of $300. This fee should be $3.

New Review of Psychiatry and Neurology.—The *Quarterly Review of Psychiatry and Neurology* will be published in January, April, July and October, according to the Washington Institute of Medicine, Washington, D. C. Dr. Winfred Overholser, Washington, is editor in chief of the new publication.

Planned Parenthood Federation.—"The Challenge of Today's Children" will be the theme of the annual meeting of Planned Parenthood Federation of America at the Waldorf Astoria Hotel, New York, January 22-23; the session will observe the twenty-fifth anniversary of the founding of the original Birth Control League of America by Margaret Sanger. The second day's subject will be "Health Hazards Facing the World's Children."

George Darling Named Executive Secretary of National Groups.—George B. Darling, Dr.P.H., formerly president of the W. K. Kellogg Foundation, who since 1943 has been associated with the division of medical sciences of the National Research Council, Washington, first as executive officer of the committees on military medicine and later as vice chairman of the division, has been appointed executive secretary of the National Academy of Sciences and of the National Research Council.

Teaching of Russian in American Universities.—Chemists studied Russian in larger numbers than did other scientists, it was revealed in a recent survey among twenty-five universities conducted by the American Association of Teachers of Slavonic and East European Languages. Biologists, including physicians and medical students, came next, followed by physicists, including radio engineers. Of the institutions covered by the inquiry, twenty-one now accept or recommend

Russian in partial fulfilment of the language requirements for graduate degrees in science. In other universities, acceptance, although not decided on, is probable. About three hundred students were studying scientific Russian in the 1944-1945 school year in these universities, and over one hundred were studying general Russian. Organization of courses in Russian for scientists, wider acceptance by American universities of Russian for graduate degrees in science, and procurement of Russian technical books and magazines are urged by the committee on teaching scientific Russian of the American Association of Teachers of Slavonic and East European Languages. The survey stemmed from a progressive recognition of the importance for American scientists of closely following the published Russian researches in their fields. The committee held a meeting in Chicago December 27-29 to discuss the need.

Special Society Elections.—Dr. Raymond C. Beeler, Indianapolis, was chosen president-elect of the American Roentgen Ray Society at its recent meeting. Dr. Ross Golden, New York, was inducted into the presidency. Other officers include Drs. Francis F. Borzell, Philadelphia, and Ellis R. Bader, Cincinnati, vice presidents; Harold Dabney Kerr, Iowa City, secretary, and James Bennett Edwards, Leonia, N. J., treasurer. The 1946 meeting will be held at the Netherland-Plaza Hotel, Cincinnati, September 17-20.——At the annual meeting of the Central Society for Clinical Research November 2-3 in Chicago Dr. Roy W. Scott, Cleveland, was named president, Dr. Carl V. Moore, St. Louis, vice president, and Dr. Ford K. Hick, Chicago, secretary-treasurer.——At the twenty-eighth annual meeting of the National Malaria Society in Cincinnati, November 13-15, Dr. Mark F. Boyd, Tallahassee, Tenn., was inducted into the presidency. Mark D. Hollis, Atlanta, Ga., was named president-elect, J. A. Mulrennan, B.S.A., Jacksonville, Fla., vice president, and Martin D. Young, Sc.D., Columbia, S. C., secretary-treasurer.——At the twelfth annual meeting of the American Academy of Tropical Medicine, held November 14 at Cincinnati, Dr. James S. Simmons, M. C., Washington, D. C., was elected president, Dr. George K. Strode, New York, vice president, Ernest C. Faust, Ph.D., New Orleans, secretary, and Dr. Thomas T. Mackie, M. C., New York, treasurer.

Insurance Research Fund Starts to Function.—Grants totaling $126,000 to be used for research into the causes of cardiovascular diseases have been made to the medical schools of six universities by the Life Insurance Medical Research Fund, it was announced December 23 by Mr. M. Albert Linton, Philadelphia, chairman of the fund. The recipients of these grants, the first to be made by the fund since its organization by 147 life insurance companies last fall, are as follows:

Drs. Joseph Victor, department of pathology, and Dickinson W. Richards Jr., department of medicine, both of Columbia University College of Physicians and Surgeons, New York.

Drs. Maurice Visscher, department of physiology, and Arthur Kirschbaum, department of anatomy, both of University of Minnesota Medical School, Minneapolis.

Dr. Henry C. Bazett, department of physiology, University of Pennsylvania School of Medicine, Philadelphia.

Dr. Gladys J. Fashena, department of pediatrics, Southwestern Medical College of the Southwestern Medical Foundation, Dallas, Texas.

Dr. John R. Smith, department of internal medicine, Washington University School of Medicine, St. Louis.

Dr. John R. Paul, department of preventive medicine, Yale University School of Medicine, New Haven.

This is the largest amount to be devoted in any one year to research in this field, with a total of $3,500,000 in prospect over a six year period. The grants made by the fund were recommended by the medical advisory committee, of which Dr. Francis G. Blake, dean of Yale University School of Medicine, New Haven, is head and approved by the board of directors. Officers of the fund elected for 1946 were Mr. Linton, president of the Provident Mutual Life Insurance Company and the chairman during the organization period, elected chairman; Leroy A. Lincoln, president, Metropolitan Life Insurance Company, vice chairman; Leigh Cruess, vice president, Mutual Life Insurance Company of New York, secretary; Morgan B. Brainard Jr., assistant treasurer, Aetna Life Insurance Company, treasurer (The Journal, Dec. 29, 1945, p. 1279).

Sugar Research Awards.—A total of $45,000 will be awarded within the next five years by the Sugar Research Foundation, New York, for the development of demonstrated original knowledge about, or practical uses for sugar in medicine, agriculture, the arts, the industries or other fields of human endeavor as judged by their importance in terms of the advancement of knowledge and of the public benefit. On or about March 1 and of each of the three succeeding years an intermediate prize of $5,000 will be given for the most important discovery or invention of the nature described which has been made during the preceding year. On March 1, 1950 a grand prize of $25,000 will be given for the most important discovery or invention which has been made during the five years preceding. An advisory committee has been created by the National Science Fund of the National Academy of Sciences, through which the awards will be administered. Members include:

A. Baird Hastings, Ph.D., Hamilton Kuhn professor of biochemistry, Harvard Medical School, Boston.

Charles F. Kettering, Sc.D., Dayton, Ohio, vice president of the General Motors Corporation and president, American Association for the Advancement of Science.

Carl S. Marvel, Ph.D., professor of organic chemistry, University of Illinois College of Medicine, Chicago, and president, American Chemical Society.

Edmund W. Sinnott, Ph.D., Sterling professor of botany, Yale University School of Medicine, New Haven, Conn.

Dr. William C. Stadie, John Herr Musser professor of research medicine, University of Pennsylvania School of Medicine, Philadelphia.

Vincent Du Vigneaud, Ph.D., professor of biochemistry, Cornell University Medical College, New York.

The Sugar Research Foundation has recently brought out a booklet concerning its prize award program and general activities. Since the organization of the foundation on June 10, 1943 it has awarded grants totaling $415,875.

LATIN AMERICA

Health Activities in Latin America.—*Examination of Food Handlers Halted Because of Cost to Government.*—Blood tests and physical examinations for food handlers in the cities of Panama and Colon have been stopped by the Department of Health for the Republic, it was announced November 10 by Dr. Alberto Navarro, director of public health. Dr. Navarro said that the tests will no longer be required because of the high cost to the government and because they have been found to be ineffective. Although the examinations have been halted, the department will continue to take measures to protect the public health, Dr. Navarro said. One of these will be a series of talks on personal hygiene to be held in various sections of the cities. Food handlers will be required to attend these lectures.

Course on Cancerology.—A postgraduate course on cancerology will be given at the Faculty of Medicine of the University of Havana for physicians of Cuba and of other countries under the direction of Dr. Nicolas P. Duany, Havana. The course will be given January 8-February 11. A diploma will be given to physicians who take the complete course. Further information can be obtained from the Secretariá de la Facultad de Medicina de la Universidad de la Habana, Havana, Cuba.

Proposed Medical Center and University.—The Venezuelan government will spend more than $10,000,000 in the construction at Caracas of a combination medical center and university which will be the largest and best equipped in Latin America, it is reported. A staff of over a hundred doctors, specializing in every branch of medicine, will be assigned to the new hospital with the purpose of improving the health rate of Venezuelan nationals. The government of Venezuela is said to be working on a national program which will greatly improve living conditions of the laboring classes.

Hospital News.—Plans are going forward for a maternity wing in the Amador Guerrero Hospital, to be known as the Roosevelt Memorial Ward.

Public Health Laboratory in the Dominican Republic.—In August 1945 an agreement was signed providing for a building to be used as a central public health laboratory of the Department of Health and Public Welfare of the Dominican Republic, according to the *Newsletter* of the Health and Sanitation Division, Institute of Inter-American Affairs. Adequate facilities for disease diagnosis by application of approved laboratory methods have not heretofore been provided, and present governmental facilities for such services are limited to certain diagnostic determinations and a restricted volume of specimen examinations. Services in the new laboratory will include clinical and laboratory examinations and related determinations as well as other public health activities, including instruction of students in laboratory technic through classes, demonstrations and practical experience and the maintenance of a library which will serve as a depository for reference material on laboratory and allied subjects. Operation of the services is to be inaugurated in accordance with an agreement between the National Department of Health and the Rockefeller Foundation, which provides funds for proper establishment of services and supervised operation for a period of three years. Construction of the building will be financed by the Servicio Cooperativo Interamericano de Salud Publica.

Government Proposal to Abolish the Sale of Medical Practices

The medical profession is concerned by the statement in the House of Commons by the minister of health, Mr. Bevan, in which he affirms that the government believes it will be incompatible with the provision of an efficient national health service for the future exchange of medical practices and the creation of new practices within that service to be left entirely unregulated. Steps should be taken to secure a proper distribution of doctors to fit the public need. Intervention in this field will probably have the effect of preventing the sale and purchase of practices by doctors taking part in the new service. The government therefore has thought it right to give this warning. But there will be an appropriate measure of compensation to doctors in respect to loss of capital value directly caused by the new arrangements.

The effect of this pronouncement produced an immediate reaction from the British Medical Association. Its secretary, Dr. Charles Hill, who is also secretary of the negotiating committee of the medical profession with the government, stated in the *Times* that compensation for loss of capital values incurred by doctors is only just. The capital represented by a doctor's practice he has paid for or built up, and he relies on it for his retirement years. When a practice changes hands, what is transferred is good will; the patients themselves are free to accept the incoming doctor or choose another as they please. Many will not share the government's view that an efficient medical service can be secured only by such a fundamental change in the existing arrangements. If the government assumes to direct doctors where and how and with what colleagues they shall practice, the proposal is fraught with danger to the public and to professional freedom. Doctors, like other workers, should be free to choose the form, place and type of work they prefer, without government or other direction. For these reasons the attitude of the medical profession to any proposal to abolish the sale and purchase of practices can be determined only when it is known what is to be substituted for the existing arrangements.

New Medical Journals

The termination of the war has allowed the British Medical Association to carry out its intention to launch three new journals, which has been discussed for the past two years. These journals are the *British Journal of Pharmacology and Chemotherapy*, the *British Journal of Social Medicine* and *Thorax*. The first is to be published in cooperation with the British Pharmacological Society and the third with the Association for the Study of Diseases of the Chest. The proposal to publish the second journal came from Brig. F. A. E. Crew, Prof. Lancelot Hogben and Sir John Orr. Papers for the first journal should be sent to Dr. H. R. Ing, Department of Physiology, Oxford; for the second, to Brig. F. A. E. Crew, Usher Institute, Warrender Park Road, Edinburgh, 9; for the third, to Mr. N. R. Barrett, F.R.C.S., 2 Dorset Street, London, W. 1.

British and American Diets Compared

An important statement comparing food consumption in Britain, Canada and the United States has been issued by the Ministry of Food. It should be realized that the food conditions existing during the war continue in Britain, where aid to Europe has impeded recovery. This year the consumption of food in Britain is lower than in the two North American countries by about 5 per cent for fats, 15 per cent for sugar, 25 per cent for meat and milk, 40 per cent for eggs, 40 to 60 per cent for fruit and 90 per cent for poultry. On the other hand, consumption in Britain exceeds that of Canada and the United States by about 20 per cent for grain products, 50 to 100 per cent for potatoes and about 300 per cent for fish. Vegetable consumption is lowest in Canada and highest in the United States. The principal change in the British diet due to the war is a great reduction in meat; the war ration of the quantity of meat which can be bought weekly for 28 cents continues. This amounts to only about ¾ pound of meat weekly. The great increase in fish consumption is compensatory. Vital statistics have actually improved during the war. The people apparently have not suffered from the severe rationing which dislocated their ordinary food habits. Bread was never rationed, and sufficient food could be obtained although not the food desired.

PARIS

(From Our Regular Correspondent)

Nov. 28, 1945.

Organization of Scientific Research in France

Frederic Joliot-Curie, professor at the Collège de France, director of the National Center for Scientific Research, reported to the congress on the work effected since the liberation. There is a National Committee for Scientific Research comprising a membership of 280 working under the direction of 15 members. The amalgamation of pure and applied research has been effected. A second innovation (which has been made only in France) is the creation of a body of technicians from every profession which will assist investigators in their research. The center has endeavored to increase the number of research workers and technicians. In this respect progress is already to be noted, for in 1943 there were 450 research workers and 500 technicians, while in 1945 there were 750 and 970 respectively. The center has prepared plans for research and the building of new laboratories, established a scientific mission to Germany which will deal with the German scientific problem and return to France the appliances seized by the Germans. The center aims to establish close relations between it and the "departments" for research existing in the various ministries. With this in view the Superior Council of Colonial Research and the committee of coordination of research relating to the national defense have been created. There is a special course for young research workers, which consists in visiting laboratories of a given specialty, the following of specialized lectures at the university and, during the second year, working in laboratories abroad. The budget for scientific research, which amounted to 250,000,000 francs in 1945 (three times more than in 1944), will be half a million francs in 1946. Joliot-Curie proposed the organization of a national center for technical research and subsequently the creation of an office or of a ministry for scientific research. He emphasized that scientists must have control over the use of their own inventions. He recommended the creation of a "council of utilization" for relations between nations.

Persisting Bone Disease Through Calcium Deficiency

By the end of 1941 warning had been given by French doctors and research workers regarding the deficiency of calcium, phosphorus and vitamin D in the food of the population and the serious consequences which would result. They made several practical recommendations, but the Vichy government ignored this danger. In 1943 and 1944 and recently in his lecture before the Congress for the Advancement of Science, Justin Besançon has, with others, stressed the persistence of bone disease. The cases especially under consideration were Milkman's syndrome, symmetrical fissures and fractures and spinal osteoporosis, a coarse type of osteomalacia of two forms: (1) pain in the low lumbar region with sacral and femoral irradiations (patients come to be treated for pains presumed by them to be rheumatism); (2) kyphoscoliotic forms with heaping up of vertebrae and diminutions of height by 10 to 15 cm. In a hospital ward and in private practice Coste and Berger found 3 cases of bone disease in 1940, 5 cases in 1941, 8 cases in 1942, 24 cases in 1943 and 51 cases in 1944. Besançon contends that this phenomenon still shows a tendency to increase. Among Coste and Berger's patients 85 per cent are over 60 years of age and 62 per cent are women. Senility and the menopause play an important part in decalcification. The authors remark that, even after the liberation, a deficit of 1 Gm. a day of calcium still exists. This deficiency of calcium, persisting for years, should result in a complete decalcification of the skeleton, but most of the undernourished bodies adapt themselves to this calcium deficiency. The authors gave their patients 3 Gm. of calcium phosphate by mouth, adding to it, three times a week, 15 mg. (60,000 international units) of vitamin D. Because of shock and tissue reactions due to the impurity of the manufactured calcium gluconate, they did not give calcium intravenously. In several instances the treatment resulted in a partial or total failure.

PREVENTIVE MEASURES

In order to prevent these deficiency diseases, the Academy of Medicine has proposed to the Food Ministry that calcium be added to the bread. Since 1942 in Britain, 0.35 Gm. of calcium carbonate has been added to 300 Gm. of bread; in France, where milk for adults is scarce the addition of calcium ought to be greater. Furthermore, because of the free sale of bread, its consumption has increased and consequently the calcium deficiency should be attenuated. In one of the last meetings of the Academy of Medicine Professor Lesne reported progress in the distribution of milk to children. Henceforth, in most of the large cities, children up to 18 months of age can have 1 liter instead of 750 cc. In various cities pasteurized milk is sold in 1 liter bottles; and in the last fourteen years pasteurization has increased considerably. There is a shortage of condensed milk for children.

PUERTO RICO

(From Our Regular Correspondent)

SAN JUAN, Dec. 23, 1945.

Annual Meeting of Puerto Rico Medical Association

The forty-second annual meeting of the Puerto Rico Medical Association was held for four days in December at San Juan. Prominent members of the American Medical Association visited the island as guests of the Puerto Rico association. Physicians from Canada, the Dominican Republic and Trinidad were also honor guests. Dr. Luis Manuel Morales of San Juan was elected president of the association for 1945-1946, with the following members as the board of directors: Dr. Julio A. Santos, vice president; Dr. Rafael A. Vilar, secretary; Dr. Ezequiel Prieto, treasurer; Dr. Carlos E. Muñoz MacCormick, speaker of the house of delegates, and Dr. José N. Gándara, delegate to the House of Delegates of the American Medical Association. At the building of the association a ceremony was held to dedicate the forty-second meeting of the association to the late Dr. Pedro Gutierrez Igaravides, prominent Puerto Rican scientist, who died in 1935.

The program included a series of conferences held at the School of Tropical Medicine in San Juan, with presentation of interesting cases by Drs. Ramón M. Suárez, Arturo L. Carrión, F. Hernández Morales, Caroline K. Pratt, Rex J. Bunker and Ramón M. Suárez Jr.; Treatment of Filarial Chyluria of Renal Origin, by Dr. Julio E. Colón; Use of the Skin Test in the Diagnosis of Schistosomiasis Mansoni, by Dr. J. Oliver González; Diagnosis of Schistosomiasis Mansoni by Biopsy of the Rectal Mucosa, by Drs. F. Hernández Morales and J. Maldonado; Treatment of Schistosomiasis Mansoni with Anthiomaline, by Drs. Federico Hernandez Morales, Ramón M. Suárez, Caroline K. Pratt and J. Oliver González, and Clinicopathologic Conference, by Drs. Franklin M. Hanger and Enrique Koppish.

The meeting also included a series of interesting conferences held at the building of the association presided over by Dr. Héctor A. Bladuell of San Juan and by Dr. Héctor Read Barreras of the School of Medicine of the Dominican Republic. The meeting adjourned with a banquet for members of the Puerto Rico Medical Association and honor guests.

BOLIVIA

(From Our Regular Correspondent)

LA PAZ, Nov. 12, 1945.

Incidence of Communicable Diseases

As the result of increasing airplane travel, every outbreak of communicable disease is of great practical interest, and preventive measures, to be effective, must be based on a rapid acknowledgment of an outbreak anywhere in the world. Here in Bolivia, the crossroad of several international air lines, several epidemic diseases have been reported during the seven month period April through October, according to figures from the National Health Department.

A fairly large incidence of bubonic plague was registered during April in the town of Vallegrande, where isolated cases have been found for years. There were 65 known cases and 34 deaths attributed to plague; a vaccine prepared by the bacteriologic institute at La Paz together with the isolation of the whole district proved to be effective in controlling the disease.

An outbreak of meningococcic meningitis occurred in and around the town of Cochabamba, an important center of communication, with its peak between June and August; there were 81 cases and 14 deaths (17.3 per cent) reported to the health authorities. The disease was spreading to other places, and by October 31 a total of 151 cases with 62 deaths had been reported from different districts of the country. Measures taken by the local health authorities were quick and efficient, while the help granted by the Servicio Cooperativo was limited to the provision of some thousands of sulfadiazine tablets.

Yellow fever, a serious menace only a few years ago, is a nearly unknown disease here now, thanks to the magnificent sanitation work performed by the Rockefeller Foundation. In a seven month period only 7 cases with 2 deaths were due to yellow fever.

Smallpox is still widespread, even though progress has been made as the result of obligatory vaccination. A total of 1,345 cases was reported during seven months, and a few cases occurred even in larger towns such as La Paz and Cochabamba.

Typhoid and parathyphoid fevers reached their peaks during April and during September and October; in the whole period there were 763 known cases with 171 deaths (22.4 per cent). Typhus became more frequent during the last two months, when 79 new cases were reported with 32 deaths. Only 38 cases with 18 deaths were reported during the previous five months.

Diphtheria was reported 291 times (49 deaths) and whooping cough 3,249 times (286 deaths). Not a single case of poliomyelitis was reported, and this disease remains practically unknown here. There were 200 cases of scarlet fever with 16 deaths, and 9 cases of acute epidemic encephalitis with 5 deaths.

Malaria is the number one health problem, and 10,032 new cases with a death rate of 108 were reported; there are probably many other people becoming infected every month who never seek medical aid and therefore are not recorded in any health statistics. A very promising malaria survey was started in May by the Servicio Cooperativo Interamericano de Salud

Pública with the aid of an American specialist, but that work was unfortunately discontinued. There is another such survey under way, sponsored by the Bolivian government.

The existing obligatory reporting system for communicable diseases, established in this country by executive order, has proved efficient, but any continuous organized interchange of epidemiologic informations with other republics of this continent does not exist at present. The work, promised by the Commission of Experts on Quarantine of the United Nations Relief and Rehabilitation Administration, is expected to be of great help.

BELGIUM

(From Our Regular Correspondent)

Nov. 10, 1945.

Poliomyelitis

Since the poliomyelitis epidemic which raged in Belgium this summer, several timely reports have been published on this subject. Kleyskens and Laruelle present several interesting opinions on the subject in the *Bruxelles médical.* The virus is widely distributed throughout the population during the epidemic. Only a small number of these carriers have the disease. The contamination by direct contact is relatively infrequent. The virus is located in the intestine and is found in the feces and in polluted water in the districts where the disease prevails. The contamination without doubt takes place through the drinking water and also perhaps through the nasal passages. Human poliomyelitis and encephalomyelitis of the mouse present great clinical, micropathologic, epidemiologic and immunologic similarities. The respective viruses have the same size and have common physicochemical properties. The comparative study of the two disorders supports the belief that poliomyelitis is caused by an intestinal infection with a pathogenic virus presenting a neurotropic character only under certain conditions. The effects of serotherapy remain doubtful, but the absence of other therapeutic means justifies its provisional utilization. On the other hand, the authors point out that in the present epidemic of poliomyelitis respiratory disturbances were of exceptional frequency and gravity. They believe that early diagnosis and analysis will permit differentiation between the spinal form and the bulbar form of this respiratory paralysis. The pathogenesis of these disturbances is equivocal. It implies, therefore, different therapy depending on the nature of the disorder.

The Professional Secret

The court of Liége has pronounced judgment in the case of a physician who was accused of violating a professional secret. The obligation of secrecy is so great that it is sanctioned in the penal code in order to protect the general interest and to give a guaranty for the confidence which the patient entrusts in his physician. Consequently the duty of secrecy must always exist excepting in the cases provided by law where the physician is not a person of confidence (legal physician). Even if the case is one of more or less public knowledge, it is not immaterial for the physician to support this knowledge by issuing statements which he possesses only by the virtue of the exercise of his profession. It is not the eventual damage to the patient which forms the basis for professional secrecy but rather consideration of the general good which demands that the secret be guaranteed. Even when a fact is known by the declaration or the agreement of physicians, the treating physician to whom the patient has made his confidences cannot be relieved of his obligation of secrecy. This is more peremptory when the agreement has not yet been established. It is not necessary that the appearing person has acted with bad intention in order that it be a violation of the professional secrecy. In the case under consideration the physician had spoken of the external wounds of his patient (this fact could be considered to a certain extent as of public knowledge) and had also made reflections on the patient's general condition. After having taken account of extenuating circumstances, the physician was sentenced conditionally to a fine (*Revue de droit pénal et de criminologie,* 19th year, No. 2, p. 324).

A History of Oppression

In a report which can serve as an example of the painful aspects of oppression, the *Bruxelles médical* published the following: "In April 1943 a plan was developed to prevent the next deportation of Jews from Belgium to Germany. It was submitted to the national commander of the Army of Partisans, who, according to the opinion of a special commission, was called on to study the undertaking, which was daring, perilous and practically impossible to execute. Dr. Youra Lifschitz, doctor of medicine at the University of Brussels, undertook the plan with his group of partisans. Several other accomplices were acquired, in particular railroad workers, who agreed to halt the train on signal. A Brussels doctor, Dr. Freddy Thys, kept himself in readiness to care for those who might be wounded.

The action was realized on April 19. In spite of heavy machine gun fire, the doors of several railroad cars were opened and hundreds of Jews included in this twentieth transport succeeded in escaping. When the convoy was again en route, numerous deportees made another effort to flee between Louvain and Tirlemont. There were about 60 dead and several dozen wounded. The Gestapo retook 7 and confined them to the guard of the director of the hospital of Tirlemont.

A new action was decided on with the view of saving them, this time in accord with the national commander of the Army of Partisans." Two vehicles were sent to Brussels so that freeing of the injured could be effected. An agent provocateur had unfortunately slipped into the group and had alerted the German police. At their return, the latter had laid an ambush. A lively engagement took place and several field gendarmes were killed. The Partisans were able to save themselves, but the injured who had been liberated were retaken and later deported. Dr. Thys was condemned to death for his intervention in this "act of terrorism"; his execution was suspended but he was deported to Germany. He has returned to Brussels, fortunately in good health, and has taken up his medical activities.

Dr. Youra Lifschitz was shot after having been tortured at Breendonck. He is buried at the side of his brother, Choura, in Brussels.

Marriages

Frederick B. Spencer Jr., Salisbury, N. C., to Miss Ernestine Lewis, Tazewell, Va., in Richmond, Va., September 22.

John Robert Massie Jr., Perkinsville, Va., to Miss Emily Charlotte Taylor of Big Stone Gap, September 15.

John Gerard Masterson, Brooklyn, to Miss Jeanne Ann O'Reilly of New Rochelle, N. Y., October 20.

Hugh B. McManus Jr., Fort Bliss, Texas, to Miss Jane Pieper of St. Louis, September 15.

Julian Menden, New York, to Miss Pauline F. Connor of Chicago in Paris, France, June 18.

Philip J. Lahey Jr., to Miss Marie Gertrude Fay, both of Worcester, Mass., September 8.

Edwin Booth Vaden, Gretna, Va., to Miss Anne Funsten Rogers of Roanoke, August 25.

Norman G. Linton, Jamestown, Ohio, to Miss Jane E. Compton of Dayton in October.

Robert D. Moreton, Temple, Texas, to Miss Alma Williamson of Eastland, September 21.

Leo Michael Smith to Miss Barbara M. Potts, both of Stamford, Conn., October 16.

Hervey Winthrop Mead to Miss Alberta Allen, both of Atlanta, Ga., recently.

Deaths

Frank Watkins Weed ⊕ Brigadier General, U. S. Army, retired, San Francisco; University of Maryland School of Medicine, Baltimore, 1903; Army Medical School in 1905 and Army War College in 1929; born in Baltimore April 12, 1881; joined and served as assistant surgeon with the Artillery Corps at Fort McHenry, Md., and at various stations in the Philippine Islands from May 1904 to the latter part of 1907; returned to the United States and served as surgeon at Field Hospital number 6, Pine Camp, N. Y., and later at Fort Totten, N. Y.; early in 1912 he again was stationed in the Philippine Islands and at Tientsin, China, until January 1915, when he returned to the United States, serving at Letterman General Hospital, San Francisco, until July 1916; served at various temporary stations until August 1918, when he was assigned as general sanitary inspector, Office of the Chief Surgeon, American Expeditionary Forces, until July 28, 1919; awarded the Distinguished Service Medal for his services during World War I; on his return to the United States served as district surgeon at El Paso, Texas, until August 1920 and as post surgeon at Fort Bliss, Texas, until July 1921; served as instructor, medical reserve units, 94th division, at Boston, as harbor defense surgeon at Fort Mills, P. I., as commanding officer at Sternberg General Hospital in Manila, P. I., as post surgeon and professor, department of military hygiene, United States Military Academy at West Point, N. Y., and as surgeon, second corps area, at Governors Island, N. Y.; promoted to lieutenant colonel in 1919, colonel in 1930 and brigadier general in 1942; fellow of the American College of Surgeons; at one time assistant and later editor in chief, Medical Department of the United States Army, in the World War; served as commanding officer of the Letterman General Hospital, where he died September 29, aged 64, of cachexia and exhaustion.

John Douglas McLean ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1894; born in Norristown, Pa., Oct. 19, 1870;; member of the House of Delegates of the American Medical Association from 1917 to 1922 and in 1924; past president of the Philadelphia County Medical Society, American Hospital [illegible] Club of Philadelphia and the Sydenham Medical Coterie, during World War I attached to the Surgeon General's Office in Washington, in charge of physicians' war assignments; discharged from service as lieutenant colonel; chairman of the local selective service board number 27 from 1940 to 1945; deputy commissioner of health of the commonwealth of Pennsylvania from 1919 to 1923; member of the board of health of the city of Philadelphia; treasurer of the Philadelphia Institute for Medical Research at the Philadelphia General Hospital, where he had been chief of staff and later consultant on the tuberculosis service; since 1898 on the staff and since 1928 medical director and superintendent of the Rush Hospital for Consumption and Allied Diseases and its country branch at Malvern, Pa.; died November 10, aged 75, of bronchopneumonia secondary to carcinoma of the pharynx.

Frank Adelbert Bien ⊕ Irvington, N. J.; New York Homeopathic Medical College and Flower Hospital, New York, 1917; born in Newark, N. J., March 14, 1890; also a graduate in pharmacy; interned at the Metropolitan Hospital, Department of Public Charities, New York; first lieutenant, medical corps of the U. S. Army, World War I, serving as commander of Base Hospital number 73 at Camp Greenleaf, Ga.; fellow of the American College of Surgeons; attending surgeon at the Irvington General Hospital in Irvington; affiliated with the Presbyterian and St. Michael's hospitals in Newark and East Orange General Hospital in East Orange; during World War II served on the Civilian Defense Council and Irvington Chapter of American Red Cross; in 1935 served in the New Jersey state assembly; died October 19, aged 55, following an operation for lung abscess.

George Jesse Wright ⊕ Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1904; born in Pittsburgh June 1, 1880; professor of neurology at the University of Pittsburgh School of Medicine; specialist certified by the American Board of Psychiatry and Neurology, Inc.;. member of the American Neurological Association, American Psychiatric Association and the Association for Research in Nervous and Mental Disease; fellow of the American College of Physicians; served as president of the Pennsylvania Psychiatric Society; neurologist, St. Margaret Memorial,. Mercy, St. Francis, Elizabeth Steel Magee and Allegheny General hospitals and St. Joseph's Hospital and Dispensary; died in the Toronto General Hospital, Toronto, Ont., Canada October 1, aged 65, of nephritis.

Douglas Hamilton Mebane ⊕ Colonel, U. S. Army, retired, Washington, D. C.; University of Texas School of Medicine, Galveston, 1916; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians and the American College of Surgeons; served during World War I; entered the medical corps of the U. S. Army as a first lieutenant in 1917; promoted through the various ranks to that of colonel; retired July 31, 1943 because of age; died in the Brooke General Hospital, Fort Sam Houston, Texas, Nov. 12, 1943, aged 56, of bronchopneumonia and arteriosclerosis.

George A. Allison, Cleveland Heights, Ohio; Western Reserve University Medical Department, Cleveland, 1895; on the medical staff of the Fisher Aircraft Plant number 1 in Cleveland during World War II; formerly examiner for the Baltimore and Ohio Railroad; died in the University Hospital, Cleveland, October 5, aged 74, of cerebral embolism.

Elizabeth S. Jarrett Anderson, Ardmore, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1898; at one time on the staff of the Norristown (Pa.) State Hospital; died September 2, aged 68, of coronary thrombosis.

Peyton Fortine Anderson, New York; New York Homeopathic Medical College and Flower Hospital, New York, 1913; associate visiting physician at the Sea View and the Harlem hospitals; vice chairman of the Harlem committee, New York Tuberculosis and Health Association; chairman of the board of managers of the Harlem Branch of the Y. M. C. A.; died October 10, aged 54, of heart disease.

Lasar Noah Andres ⊕ New York; Northwestern University Medical School, Chicago, 1911; specialist certified by the American Board of Otolaryngology; served during World War I; on the staff of the Manhattan Eye, Ear, Nose and Throat Hospital; died October 15, aged 63, of coronary occlusion.

Ray Beardsley, Binghamton, N. Y.; Long Island College Hospital, Brooklyn, 1895; member of the American Medical Association; once president, secretary and treasurer of the Broome County Medical Society; served as city physician; died September 7, aged 80, of arteriosclerotic heart disease.

Adolphus Lyman Biggs, Dayton, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; member of the American Medical Association; died in the Good Samaritan Hospital September 24, aged 63, of coronary occlusion.

Pat Biscoe, Houston, Texas; University of Arkansas School of Medicine, Little Rock, 1926; member of the American Medical Association; interned at the Hotel Dieu Hospital in New Orleans; formerly resident physician at the International and Great Northern Railroad Employees' Hospital in Palestine; member of the staff as associate surgeon at St. Joseph's Infirmary; died October 16, aged 49, of coronary occlusion.

Carl Gottlieb Bretthauer ⊕ Los Angeles; State University of Iowa College of Medicine, Iowa City, 1920; died in Santa Monica September 21, aged 50, of cerebral hemorrhage.

Francis Sidney Brodrick, Boston; Detroit College of Medicine, 1895; member of the American Medical Association; served as assistant superintendent of the Boston City Hospital; died in Waltham, Mass., September 11, aged 78, of coronary thrombosis.

John Francis R. Brubaker ⊕ Hubbard, Iowa; College of Physicians and Surgeons, Baltimore, 1885; member of the school board; died October 11, aged 86, of senility.

Clarence Walter Byers, Rutherford, N. J.; Long Island College Hospital, Brooklyn, 1902; served as examining physician for the city draft board number 16; president of the board of health, police surgeon and lieutenant in the New York National Guard; past president of the Rotary Club; for many years affiliated with the Holy Name Hospital, Teaneck, where he died October 25, aged 67, of Parkinson's disease.

Philip L. Cain, Albany, Okla. (licensed in Oklahoma under the Act of 1908); member of the American Medical Association; died August 21, aged 84.

Julian H. Chandler, Swainsboro, Ga.; University of Georgia Medical Department, Augusta, 1901; member of the American Medical Association; died August 20, aged 66.

Edwin W. Coffey, Shreveport, La.; College of Physicians and Surgeons, Dallas, Texas, 1908; died September 25, aged 68.

John McGrath Collins ⊕ San Francisco; Creighton University School of Medicine, Omaha, 1935; also a graduate in pharmacy; interned at the Southern Pacific General Hospital; later served a residency at St. Francis Hospital, with which institution he was closely connected and where he died September 2, aged 36, of miliary tuberculosis.

John Leader Corish, Richmond Hill, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1887; died September 28, aged 80.

Thomas E. Courtney ⊕ Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1892; formerly on the faculty of his alma mater; at one time police surgeon and member of the city board of health; examined army recruits during World War I; on the staffs of St. Francis Hospital, City Hospital, Methodist Hospital and St. Vincent's Hospital, where he died September 27, aged 77, of coronary thrombosis.

George William Dickey, Westville, Okla.; Tennessee Medical College, Knoxville, 1904; died August 18, aged 64, of cerebral hemorrhage.

Benjamin Roscoe Dodd, Wake Forest, N. C.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1925; died in Lenoir recently, aged 46, of coronary thrombosis.

Green Berry Dorrell, Tulsa, Okla.; Bellevue Hospital Medical College, New York, 1889; died in the Hillcrest Hospital September 3, aged 83, of angina pectoris and generalized arteriosclerosis.

Edwin T. Ealy ⊕ Barnesboro, Pa.; Chicago College of Medicine and Surgery, 1906; served as a member of the Barnesboro Council; died September 27, aged 70, of coronary thrombosis.

William Banks Fuller, Oklahoma City, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1923; died in St. Anthony Hospital August 8, aged 47, of cerebral hemorrhage.

Richard Burtch Gannon, Gary, Ind.; Loyola University School of Medicine, Chicago, 1937; member of the American Medical Association; interned at the Mercy Hospital in Chicago; on the staffs of the Methodist Hospital and St. Mary's Mercy Hospital, where he died September 20, aged 41, of acute myelogenous leukemia.

Milton Adolph Gershel ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1900; for many years physician for the Hebrew Sheltering Guardian Society Orphan Asylum at Pleasantville, N. Y.; died September 7, aged 70.

Thomas Byron Gold, Shelby, N. C.; North Carolina Medical College, Charlotte, 1911; member of the American Medical Association; awarded the Congressional Medal of Honor, the Distinguished Service Cross and the Croix de Guerre for services during World War I; served as chairman of the school and draft boards; on the staff of the Shelby Hospital; died September 28, aged 57, of cerebral hemorrhage.

William L. Gravlee, Orange City, Fla.; University of Nashville Medical Department, 1882; Vanderbilt University School of Medicine, Nashville, Tenn., 1882; died September 23, aged 86, of carcinoma of the right hand.

Thomas Hardie Hawkins, Nashville, Tenn.; University of Nashville Medical Department and Vanderbilt University School of Medicine, Nashville, 1891; died in the Central State Hospital September 25, aged 74, of myocardial degeneration.

Ralph Ernest Dudley Hawley, St. Clair Shores, Mich.; University of Michigan Medical School, Ann Arbor, 1920; member of the American Medical Association; died in St. Mary's Hospital, Grand Rapids, September 21, aged 69, of atypical virus pneumonia.

Rosser Noland Hillsman Jr. ⊕ Bon Air, Va.; University of Virginia Department of Medicine, Charlottesville, 1933; died in Lynchburg August 31, aged 37, of nephritis.

Harvey Elmer Hoffman, Ludington, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1890; served for many years as health officer of Ludington and as president of the board of education; a member of the local draft board, serving as examining physician during World War I; on the staff of the Paulina Stearns Hospital; died September 5, aged 78, of carcinoma.

Emil John Hoglund, Oak Park, Ill.; Northwestern University Medical School, Chicago, 1905; served during World War I; served on the staffs of the Illinois Central and Augustana hospitals and the Home for Destitute Crippled Children in Chicago; died September 27, aged 75, of heart disease.

Bradley Hartman Hoke, Meyersdale, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1901; member of the American Medical Association; secretary of the Somerset County Medical Society; served during World War I; died in the Memorial Hospital, Cumberland, Md., August 22, aged 73, of uremia following a prostatectomy.

Park Rowe Hoyt, Laconia, N. H.; Dartmouth Medical School, Hanover, 1906; member of the American Medical Association; served during World War I; died August 31, aged 63.

Heman Humphrey ⊕ Louisville, Ky.; University of Louisville Medical Department, 1904; formerly adjunct professor of anatomy at his alma mater; physician for the Louisville Gas and Electric Company, Kentucky and Indiana Terminal Railroad and the Louisville Water Company; died September 3, aged 65, of hypertensive heart disease.

Burdette Elmerin La Due, Sterling, Ill.; Rush Medical College, Chicago, 1885; died September 9, aged 92, of arteriosclerosis and uremia.

John Francis Lambert, Newark, N. J.; Baltimore Medical College, 1903; died in St. Michael's Hospital September 12, aged 66, of cardiac failure and arteriosclerosis.

Tom Lowry ⊕ Oklahoma City; University of Oklahoma School of Medicine, Oklahoma City, 1916; dean and professor of clinical medicine at his alma mater; specialist certified by the American Board of Internal Medicine; past president of the Oklahoma County Medical Society; fellow of the American College of Physicians; served in France during World War I; on the staffs of St. Anthony and University hospitals; died December 11, aged 54, of coronary thrombosis.

William Nicholas Maloney, Cape Vincent, N. Y.; Bellevue Hospital Medical College, New York, 1898; member of the American Medical Association; past president of the Jefferson County Medical Society; for many years health officer; served during World War I; on the staffs of the Mercy Hospital and the House of the Good Samaritan in Watertown, where he died September 4, aged 73, of uremia.

John Harold Mansfeldt ⊕ San Francisco; Stanford University School of Medicine, San Francisco, 1927; began active duty as a captain in the medical corps, Army of the United States, on Sept. 20, 1942; relieved from active duty on May 23, 1943; died in Shelter Cove, October 4, aged 48.

Charles Steim McGivern, Margate City, N. J.; Medico-Chirurgical College of Philadelphia, 1912; specialist certified by the American Board of Otolaryngology; died September 14, aged 60, of cerebral hemorrhage and old coronary thrombosis.

Thomas Theodore McKinney, Denver; Meharry Medical College, Nashville, Tenn., 1895; served on the staff of the Denver General Hospital; died August 7, aged 75, of hemiplegia.

Edward V. Milholland, Baltimore; University of Maryland School of Medicine, Baltimore, 1895; medical and surgical director of the Baltimore and Ohio Railroad; died in the University Hospital September 11, aged 71, of acute genitourinary infection and chronic cardiovascular disease.

John H. Newth, Pittston, Pa.; College of Physicians and Surgeons, Baltimore, 1896; died August 3, aged 72, of carcinoma of the stomach.

Horace Poirier, Salem, Mass.; Laval University Faculty of Medicine, Quebec, Que., Canada, 1902; member of the American Medical Association; president of the Essex South District Medical Society, 1939-1940, and nominating councilor from 1940 to 1941; since 1927 on the regular medical staff of the Salem Hospital, where he had been chief of obstetrics; member of the chamber of commerce; died in Conway, N. H., August 14, aged 67, of coronary occlusion.

David Phillips Pruett, Newton, Ala.; Medical College of Alabama, Mobile, 1906; member of the American Medical Association; died September 8, aged 63, of paralysis agitans.

Milton Rice, Hilo, Hawaii; Hering Medical College, Chicago, 1895; on the staff of the Hilo Memorial Hospital; for many years an officer of the chamber of commerce; president of the board of trustees of the public library; died September 19, aged 81.

William Eugene Rink, Burlington, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1903; served overseas during World War I; member of the board of health of Burlington; on the courtesy staffs of Zurbrugg Memorial Hospital, Riverside, and the Burlington County Hospital in Mount Holly; died September 26, aged 65, of carcinoma of the bladder.

Daniel Lee Rogers, Bolton Landing, N. Y.; University of Vermont College of Medicine, Burlington, 1886; member of the American Medical Association; served as health officer and county coroner; on the staff of the Glens Falls (N. Y.) Hospital; died in the New England Baptist Hospital, Boston, September 11, aged 83, of carcinoma.

Franklin Henry Rosebrough ⊕ San Antonio, Texas; St. Louis University School of Medicine, 1904; member of the American Academy of Ophthalmology and Otolaryngology; on the staffs of the Medical and Surgical Memorial Hospital and the Nix Hospital; specialist certified by the American Board of Ophthalmology; died September 16, aged 67, of heart disease.

Samuel Fellows Round ⊕ Braddock, Pa.; University of Pittsburgh School of Medicine, 1921; interned at St. Francis Hospital, Pittsburgh;; died September 8, aged 49, of hypostatic pneumonia and acute hepatitis.

Harry William Routledge ⊕ Birmingham, Ala.; University of Louisville School of Medicine, Louisville, Ky., 1928; interned at the Hillman Hospital and the Norwood Hospital, where he died August 5, aged 40, of heart disease.

Eugene Boutelle Sanger, Bangor, Maine; Columbia University College of Physicians and Surgeons, New York, 1894; honorary member of the Maine Medical Association; member of the American Medical Association; fellow of the American College of Surgeons; on the staff of the Eastern Maine General Hospital; died September 11, aged 74, of cerebral hemorrhage.

Nicholas Schilling ⊕ New Hampton, Iowa; John A. Creighton Medical College, Omaha, 1896; past president of the Chickasaw County Medical Society; fellow of the American College of Surgeons; served on the staff of St. Joseph's Hospital, where he died September 2, aged 77,.of cystitis.

Homer Talmadge Scott, Cowpens, S. C.: Atlanta College of Physicians and Surgeons, 1912; died September 1, aged 59, of coronary disease.

Harold Waldron Seff, Delaware, Ohio; General Medical College, Chicago, 1924; city and county health commissioner; for two years with the Chicago Health Department; in 1929 and 1930 in public health work in Cleveland and later associated with the state department of health; died August 21, aged 55.

Owen Malcom Shreve ⊕ Erie, Pa.; University of Buffalo School of Medicine, 1892; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Ophthalmology; for many years on the staff of St. Vincent's Hospital; died September 7, aged 84, of myocardial failure.

Jules J. Siffer, Monroe, Mich.; Detroit College of Medicine, 1901; member of the American Medical Association; formerly city commissioner; at various times health officer; one of the founders of the Mercy Hospital, where he served as chief of staff; died in St. Vincent's Hospital, Toledo, September 13, aged 67, of pneumonia.

John Gorse Simmons ⊕ New York; College of Physicians and Surgeons, Baltimore, 1891; served on the staffs of the Bronx Eye and Ear Infirmary and the New York Post-Graduate Medical School and Hospital; died in the Fordham Hospital September 28, aged 77, of arteriosclerotic heart disease.

Harry Jerome Smejkal, Chicago; Dearborn Medical College, Chicago, 1907; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; died in the Hospital of St. Anthony de Padua October 3, aged 63, in a diabetic coma and of carcinoma of the submaxillary gland.

Martin Luther Steele, McComas, W. Va.; Bennett Medical College, Chicago, 1914; died suddenly, September 19, aged 70, of coronary thrombosis.

Fred James Black
Surg., U. S. P. H. S., 1905-1944

George Charles Stoll, Niagara Falls, N. Y.; University of Buffalo School of Medicine, 1929; member of the American Medical Association and the Niagara Falls Academy of Medicine; secretary-treasurer of the Niagara County Medical Society; interned at Buffalo General Hospital; served a residency at the Children's Hospital in Buffalo; on the staffs of the Mount St. Mary's and Memorial hospitals; died September 27, aged 40, of coronary thrombosis.

Wesley M. Stone, Dobson, N. C.; Davidson School of Medicine, 1906; honorary member of the Hugh Chatham Memorial Hospital in Elkin; died September 27, aged 73.

Opie William Swope ⊕ Wichita, Kan.; Maryland Medical College, Baltimore, 1905; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc., and the American College of Radiology; staff member and radiologist to the Grace and St. Elizabeth Mercy hospitals, Hutchinson; member of the staff of the Sedgwick County Hospital and the Wichita Hospital, where he died December 12, aged 64, of diabetes mellitus complicated by cerebral hemorrhage.

Walter Lorenzo Taft, St. Cloud, Minn.; Marquette University School of Medicine, Milwaukee, 1913; for a number of years a patient in the Veterans Administration Facility, where he died September 10, aged 62, of bilateral bronchopneumonia.

Isaiah Ulysses Temple, Pendleton, Ore.; University Medical College of Kansas City, Mo., 1898; for many years associated with the Indian Service; formerly city health officer; died in St. Anthony's Hospital, August 29, aged 77.

Thorvald Martinius Thorkelsen, Minneapolis; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1902; died in Robbinsdale September 20, aged 76, of coronary thrombosis.

Gilbert Dillon Waite, Portsmouth, Ohio; Rush Medical College, Chicago, 1918; member of the American Medical Association; served as chief of the Mercy Hospital; found dead September 29, aged 51.

Carl Watson, Findlay, Ohio; Cleveland Homeopathic Medical College, 1901; captain, medical corps, U. S. Army during World War I; active in Democratic politics for twenty-five years, serving as chairman of the Hancock County Executive Committee and in 1933-1934 as state chairman; formerly works progress administrator; died August 17, aged 68.

Clara B. Woodward, Evanston, Ill.: Jenner Medical College, Chicago, 1910; died in the Presbyterian Home October 19, aged 76, of carcinoma of the uterus.

Clarence Field Worthen, Boston; Harvard Medical School, Boston, 1908; member of the American Medical Association and the New England Ophthalmological Society; ophthalmic surgeon at the Massachusetts Eye and Ear Infirmary, Boston, oculist at the House of Mercy Hospital, Pittsfield, and ophthalmologist at the Newton Hospital, Newton, Mass.; died in Braintree August 22, aged 65, of hypertensive heart disease.

PUBLIC HEALTH SERVICE

Fred James Black ⊕ Surgeon, U. S. Public Health Service, Federal Security Agency, Manila, P. I.; University of Michigan Medical School, Ann Arbor, 1932; served his first year's internship in the U. S. Marine Hospital at Norfolk, Va., and a second year's internship in the U. S. Marine Hospital in Detroit; in June 1937 commissioned an assistant surgeon in the regular corps of the public health service and detailed to the U. S. Quarantine Station, Gallops Island, Boston; in November 1937 assigned to the U. S. Marine Hospital in Memphis; on July 16, 1938 promoted to passed assistant surgeon and in 1939 assigned to the U. S. Marine Hospital in Baltimore; ordered to Manila on Aug. 1, 1940; early in 1942 officially detailed to the U. S. Army Medical Department at the request of General MacArthur; on April 1, 1943, while a prisoner of the Japanese, promoted to the rank of surgeon; on duty in Manila, was one of six public health officers in the Philippines who voluntarily offered their services to General MacArthur when the islands were invaded; subsequently assigned to a Bataan field hospital and was taken prisoner when Corregidor fell to the Japanese; killed in action in the China Sea Oct. 24, 1944, aged 39, when a Japanese prisoner of war ship, with 1,775 prisoners of war aboard, was sunk by submarine action 200 miles from the Chinese coast.

Correspondence

STATISTICS ON DIABETES IN INDUCTEES

To the Editor:—Spellberg and Leff in The Journal, Sept. 22, 1945, reported the incidence of diabetes mellitus and glycosuria among 32,033 consecutive selectees aged 18 to 35 who were "processed" at the New Orleans induction station. Only 37 instances of glycosuria were found (1.15 per thousand), of which a mere 9 proved to be diabetic (0.3 per thousand). They point out that their figures are much lower than the figures from the Boston induction center, where Blotner and Hyde (The Journal, June 12, 1943, p. 432; *New England J. Med.* **229**:885 [Dec. 9] 1943) found 367 cases of glycosuria among 45,650 selectees (8 per thousand), of whom more than half, or 208, had diabetes (4.5 per thousand). They ask "Why is there so much discrepancy between our findings and those of the New England workers?" and then attempt to find the answer in age, race and geography.

Neither of the reports as published supplies a full and complete description of the inductee groups under analysis. Were all draft-eligible males in the respective geographic areas recipients of a careful physical examination including a urine analysis at their community Selective Service offices prior to reporting to the regional induction centers? If so, this prior examination would have weeded out most of those having diabetes mellitus and renal glycosuria. The incidence of these conditions among the inductees would then not be representative for the respective regions of the country but solely for selected populations of men pronounced healthy by medical check-ups performed in the preceding few weeks. Were this true, the discrepancies would reflect gravely on the skill of New England doctors!

More likely the proportion of selectees given preinduction medical examinations, and the percentage of these tested by urine analysis, must have been lower in the Boston area in 1943 than in the New Orleans area in 1945. To a speculative reader this consideration would seem of major importance in producing the differences between the two sets of data.

In passing we may be reminded that the absence of a positive sugar reaction from a random single specimen of urine is not an absolute criterion for ruling out diabetes or other forms of melituria.

Authors and editors, in papers statistical,
Should always publish all data applicable!

Irving J. Wolman, M.D., Philadelphia.

CHRONIC ONYCHOMYCOSIS

To the Editor:—In a communication to The Journal, July 7, 1945 (p. 750), it should have been less equivocally stated that an operation for permanent ablation of the nails in chronic onychomycosis is recommended only in toe infections. Moreover, less radical measures are permissible in toe cases if the infection is relatively superficial or involves only the distal portion of the nail. Characteristically, however, these cases present themselves with the nail or nails wholly involved. The case cited by Dr. Montgomery (The Journal, Oct. 27, 1945, p. 647) in which 7 of 9 infected toe nails in a single patient were cured by conservative measures cannot realistically be considered a cure either by patient or by physician, since a single infected nail will sustain activity in the concomitant epidermophytosis and will in due course reinfect the "cured" nails. It may be emphasized that patients treated by permanent nail ablation were completely cured of the skin involvement. It now seems evident that a high percentage of chronic, recurring or relapsing cases of epidermophytosis and the epidermophytidides, competently treated without permanent success, are actually in a state of continuous or intermittent exacerbation by unrecognized or undertreated toe nail infection.

With respect to freezing of skin lesions by ethyl chloride, failure to effect cure in cases which have come to my attention has been due to insufficient refrigeration. The original technic (*South. M. J.* **23**:1128 [Dec. 12] 1930) called for daily freezing of thirty to sixty seconds duration. Timing should begin after the skin has become white. The frozen zone should extend not less than 0.5 cm. beyond the known border of infection. Six to ten or more daily applications may be required. Some recent papers have advocated daily freezing only to the extent of producing the white flare. This is not adequate therapy for many chronic infections.

The singular and very rare instances in which this treatment is not effective are those of massive plantar hyperkeratosis with a centimeter or more of coriaceous epidermis interposed between the physical agent and the infecting organism. These cases require extensive and repeated chemical and surgical "peeling" before freezing may become effective.

Properly used, refrigeration gives results as favorable as one can expect of a therapeutic agent in any field; it seems definitely superior to other physical or chemical applications.

K. P. A. Taylor, M.D., Clearwater, Fla.

HERNIATION OF FASCIAL FAT AND LOW BACK PAIN

To the Editor:—In the article by Herz in The Journal, July 28, 1945, he states that "the literature and anatomy textbooks were searched for an adequate explanation of the clinical results, but none was found until the article by Copeland and Ackerman appeared." The latter authors (*Quart. J. Med.* **13**:35 [April-July] 1944) "believe that the ground covered by this study has not been systematically explored. The work has been carried out during active service in an area in which the impossibility of access to medical literature explains the lack of references to any relevant papers."

I am willing to agree that Copeland and Ackerman may not have had access to the literature, under their circumstances, but it seems that Herz, in Cleveland, should have referred to the *Quarterly Cumulative Index Medicus*, volume 22, 1937, and here under "lipoma and E. Ries (Chicago)" one is referred to the *American Journal of Obstetrics and Gynecology* **34**:490-494 (Sept.) 1937. In this article, written over eight years ago, it will be found that the gross and microscopic findings are described, that the frequency in 1,000 cases is given, that herniation of the fatty tumors through the fascia is relatively infrequent and that symptoms may not be present at all.

Philip Lewin, in his book entitled "Backache and Sciatic Neuritis," page 617, published by Lea & Febiger in 1943, also mentions these episacroiliac lipomas and the work that we have done.

and the Swedish Covenant Hospital.

BLOOD TYPING

To the Editor:—In Dr. Harville's article on cord transfusions (The Journal, Nov. 17, 1945, p. 801) is found the statement that the blood group of the father was type O, of the mother type AB and of the child type O. According to the accepted theory of Bernstein of the heredity of the blood groups, this is impossible. One of his fundamental laws is that an AB parent cannot have an O child. While this statement is not important in the otherwise excellent article, it could be of very great importance when used by a lawyer or an expert testifying in cases of disputed paternity or maternity. A few instances like this would have the same weight in court as a hundred thousand correct findings Since this was a side issue in the article, the various blood groups have not been carefully studied and checked. In Wiener's book on "Blood Groups and Transfusion," he states that any apparent exception to Bernstein's theory should be analyzed in the following way· 1. Complete examination of cells and serum, with several sets of reagents 2. Examination of specimens taken at different intervals, especially of infants whose blood groups may not be fully developed 3 Confirmation by workers with great experience. 4 Determination of the subgroup of any group A or group AB bloods in question 5. Complete study of the family Since this family is in New York State and there are mother, father and five children to study, this should be done and the results of the study published in THE JOURNAL.

JAMES D. EDGAR, M.D., San Diego, Calif

Bureau of Investigation

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are abstracts of three such fraud orders

Brother W. Thompson-El.—From Philadelphia this person sold through the mails a booklet entitled "The Key to Retaining Eye Vision," in which he referred to himself as author and as "Minister of Islam" The booklet advertised, "Age does not matter and you are not taking chances, for it is Nature's own way of preserving eyesight . . If there are cataracts on the eyes, they are relieved . . No glasses or medicine required! REMEMBER, glasses are only crutches for the eyes . . ." A customer who ordered the booklet for $3 found that it consisted of 15 printed pages containing many quotations from the Bible and the Koran, and referred to the author as a "Divine Minister" The system of eye treatment that it presented recommended exposing the eyes to the sun as much as possible, looking at its rays in the *morning* "just a little at a time" and repeating this process "fifteen minutes two times a day the first two weeks" and gradually increasing it to one hour two times a day, to the accompaniment of sun baths This, the "Brother" claimed, would bring the eyes to their natural *strength*, the required time depending on age, the condition of the eyes at starting treatment and general health Meantime the patient could gradually *discard* his glasses, if any. As for cataract, it was claimed that "constant sunbath will remove it, but you must start in a little at a time . . generally, it requires two or three years" In view of the foregoing, it is not surprising that the Post Office Department after investigating this business, notified Brother W Thompson El to show cause why a fraud order should not be issued against him He made no appearance at the hearing held in Washington Dec. 6, 1943, but was represented by counsel A Senior Medical Officer of the Food and Drug Administration, who was qualified as a government witness from the standpoint of education and experience, testified that in his years of practice he had studied and treated eye disorders, that these arise from many causes and are not amenable to any single treatment, that when due to systemic diseases they should be treated according to their causes, that in most cases of defective vision due to the formation of the eyes, glasses are required as a correction, that cataracts occur more frequently in persons whose eyes are exposed to constant light or heat than others, and are more prevalent among persons living in desert areas affording almost constant glare from the sun than those in other sections Further, he testified that, in his opinion, the treatment in question would not cure any disease or condition of the eyes, that the recommended use of sunlight was grossly unscientific and could be harmful or dangerous, and might even *result in permanent blindness due to* irritation if the treatment were regularly followed The defense attorney presented no testimony and, though *given until Jan 12, 1944, to submit* whatever brief, argument or proposed finding of fact and of law he might desire, he merely replied on *Jan 10, 1944, that no brief would be filed* Accordingly, the business was declared to be a scheme for obtaining money through the *mails* by means of false and fraudulent pretenses, representations and promises, in violation of the federal laws, and a fraud order *was issued* May 16, 1944, debarring Brother W Thompson El from further use of the mails.

Kolontone Company.—A Los Angeles chiropractor, one W H Graves, operated this concern, also doing business simply as "Kolontone" and "Koloneulture" Possibly he is the same W H. Graves who has conducted "health columns" in at least two Hollywood publications of the "health fads" type. Originally, the chiropractor sold through the *mails* a treatment composed of two products, "Mucelim" and "Acidophilus," and in 1941, when the Post Office *Department ordered* him to show cause why a fraud order should not be issued against his enterprise because of false and fraudulent *representations that he* was making for his nostrums, he signed an affidavit to discontinue the business, with the provision that a fraud order *should* be issued against it if it were ever resumed About two years later the Post Office Department obtained evidence that Graves was *still operating* the scheme but using the new names given above, and he was again ordered to show cause by a certain date why he should *not be debarred* from the mails because of fraud At the hearing of the case a chemist testified for the government that Kolontone was a *brown* watery solution containing, per 100 cc, 0 04 gram of calcium chloride, 0 24 gram of ferrous sulfate, 0 11 gram of sodium *chloride and 12* grams of glycerin, with a trace of carbonate and some protein digestives The directions were to mix 1 ounce of *Kolontone* with 1½ pints of warm water and allow it to run into the colon following an enema, once a day "until all mucus, putrid gas *forming* matter or dark fecal impactions and bad odors will have been eliminated" In addition, "to help maintain normal *chemistry of the* colon, to help control the putrefactive bacteria and to aid good bowel action in the future, several bottles of Koloneulture should be *implanted* in the colon at the conclusion of the Kolontone cleansing" A qualified bacteriologist testified for the government that microscopic analysis had shown the presence of bacillus acidophilus in Koloneulture, described as "a gold colored fluid" An expert medical witness *for the government* testified on the types of colitis, stating that it is a dangerous affliction which may vitally affect the health of the *individual and in some cases* even result in death, and that certain symptoms commonly attributed by lay persons to constipation may, on the contrary, be evidence *of* disorders much more serious Hence the victim of colitis, instead of attempting to diagnose his condition and dose himself with "patent *medicines*," should have scientific treatment adapted to his individual needs The witness further showed that Kolontone, when used as directed, had practically no other effect than an enema of warm water, and that Koloneulture, whether injected in the rectum or taken by *mouth*, would be of no benefit The bacillus acidophilus that it contains, he stated, was only between $\frac{1}{50}$ and $\frac{1}{40}$ of the amount *required* for effective therapeutic use In addition, he attested that the dietary suggestions sent out by Graves were unsuitable for indiscriminate use by any *person* suffering from colitis, since some of the foods *recommended* might contain altogether too much cellulose and roughage *for such* persons Although W H Graves had made some *reply by mail to the government's* charges, neither he nor his counsel appeared at the hearing The Post Office Department declared that the charges against Graves' concern were fully sustained by the evidence presented, and accordingly, on Oct 5, 1944, issued a fraud order against Kolontone, Koloneulture and the Kolontone Company debarring them from further use of the mails

C. Frank Langley —*From Topeka Kan, Langley promoted* a mail order scheme, selling under the *name* "Secrits" a series of formulas under the *designations A, B, B1, C, D and E These represented, respectively,* a "cheap fluid that makes Varicoses feel normal", "a cheap, powerful, harmless fluid that *permanently Removes Cataracts and strengthens eyes*", a formula "for clearing and strengthening eyes", one designated "cat, dog or monkey scratches or bites cured", another, *described* as "deep wounds and running sores healed," and the last one, an alleged cure for granulated eyelids Langley's "offer" included "all 6 above guaranteed money back for failures," and stated that he would furnish ingredients on request, at an extra charge To a person who wrote Langley regarding a cataract for which an operation had been advised, he replied with a two page *letter* written in longhand and a printed circular. The letter gave the assurance "You order the Formula (B) Use it according to Directions, get the Cataract out *of* your Own Eye, and then you'l be like other People I'v helped There is an Ingredient in (B) that shrinks the Cataract just enough to make it Brake Ez Another Brakes it and another Pushes it out of the Eyelids Continued Use of (B) Heals, and Strengthens the Sight" In reply to another inquiry, Langley wrote in longhand as follows "When you Use B be shure to get all the Ingredients Under Your Eyelids, try to hold it *3* to 5 seconds You can feel the Sulfur roll around, and it will push the Cataract of from the Eveball, it comes out looking like little balls of puss" It is not surprising that investigation of this obvious quackery by the Post Office Department resulted in a notice from that agency to Langley to show cause why *a fraud order should not be issued against him* He neither put in an appearance nor sent counsel to represent him, and when a transcript *of the hearing was sent to him and he was given* an opportunity to submit any *reply* that he desired he simply returned the transcript without any *letter or brief* Previously, however, he had sent the Post Office Department a declaration to the effect that his business had been discontinued prior *to* September 1943 and that even when it was still being conducted, he had made no false or fraudulent promises through the mails *This claim* was disproved by *means* of testimony given at the hearing of the case by witnesses for the government One of these, a chemist of the Food and Drug Administration, testified that he had made a chemical analysis of the product purchased from Langley by a person who ordered it *for the* removal of cataract, and that it was a yellowish white powder consisting of *75* 28 per cent of sugar, 24 60 per cent of sulfur, and 0 12 per cent of acid insoluble material, apparently either silica or sand *The other government* witness, a Senior Medical Officer *of* the Food and Drug Administration, testified on the nature and *treatment of cataracts He further* testified that the only cure for a cataract is the removal by *operation* of the lens of the eye or such *part thereof as may be cutting out* the light from the retina He added that he was familiar with the ingredients *of the nostrum in* question, and that, in his opinion, the application of this or any other form of medication to the external surface of the eyeball between the eyelid and the cornea would be utterly unscientific and ridiculous On May 27, 1944, the Post Office Department debarred Langley's business from the mails by issuing a fraud *order* against t

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Taxation: Exemption of Charitable Hospital from State Use Tax.—The Oklahoma Tax Commission assessed a use tax against the Baptist General Convention of Oklahoma by reason of goods purchased outside the state for use and consumption within the state by the Oklahoma Baptist Hospital, which it operated. From an order approving such assessment, the plaintiff appealed to the Supreme Court of Oklahoma.

Section 6, subdivision (i) of the Sales Tax Act (S. L. 1937, ch. 66, art. 10, p. 445) provides:

> There is hereby specifically exempted from the tax imposed by this Act the following:
>
> (i) The gross receipts or gross proceeds derived from the sale of tangible personal property, or service to charitable organizations, except where such organizations may be engaged in business for profit or savings, competing with other persons engaged in the same or similar business.

The plaintiff contended that it was exempt from the tax on the ground that "it is not engaged in business for profit or savings" in the operation of the Oklahoma Baptist Hospital. In support of this contention, evidence was introduced to the effect that during the year involved in this action the hospital was operated at a net loss of over eight thousand dollars, and that during the period from 1931 to 1940, the loss was over twenty-one thousand dollars. The evidence also showed that it was the hospital's policy not to refuse a patient because of inability to pay and that the plaintiff and other direct contributors had donated over one hundred and six thousand dollars toward the upkeep of the hospital during such nine year period. In calculating the amount of loss referred to, two items were taken into consideration, bond interest and expense and depreciation. The tax commission contended (1) that such items should not properly be considered in calculating loss and (2) that whether or not a profit was made is not material in determining whether or not a hospital is operating "for profit or savings."

The Supreme Court said that the intent of the legislature was clearly expressed when it said that charitable organizations were exempt if not engaged in business for profit or savings. Of course, continued the court, a loss for one year would not prove that an organization was not engaged in business for profit but would prove only that a loss was sustained during the one year. But if such an organization continued to operate for a period of years, and year after year sustained a loss, then the only reasonable and logical conclusion to reach would be that profit or savings was not the objective of the organization, but that some other motive prompted its existence and survival. The court then held that although bond expenses were not an allowable item in determining whether or not the hospital was operating at a profit, depreciation was. We reach this conclusion, said the court, because profit or savings implies a gain resulting from the employment of capital. In the instant case it means a pecuniary gain resulting from the operation of the hospital. Allowance for depreciation is the sum which should be set aside for the taxable year in order that, at the end of the useful life of the business equipment, the aggregate of the sums set aside will (with the salvage value) suffice to provide an amount equal to the original cost. Since profit does not refer to what is already owned but is an accretion to what is already possessed, said the court, a distinction is made between money paid on bonded indebtedness and money set aside for depreciation, to replace that which is already owned. Allowing the deduction of the item for depreciation, therefore, the record showed that the hospital operated at a loss not only during the taxable year but for nine consecutive years. The court accordingly concluded that the plaintiff was not operating the hospital for profit or savings and the judgment for the defendant was reversed.—*Baptist General Convention v. Oklahoma Tax Commission, 162 P. (2d) 1012 (Okla., 1945).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Board in Specialties were published in The Journal, Jan. 5, page 50.

BOARDS OF MEDICAL EXAMINERS

Alabama: Mar. 19-21. Sec. Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.

Alaska: Juneau, March 5. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Arkansas:* Little Rock, June 6-7. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana.

California: *Written.* Los Angeles, March 11-14. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

Connecticut:* *Medical. Examination.* New Haven, March 12-13. *Endorsement.* New Haven, March 26. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, March 12-13. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

Delaware: Dover, April 16. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

District of Columbia:* *Reciprocity.* Washington, March 11. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

Florida:* Jacksonville, June 24-25. Sec., Dr. Harold D. Van Schaik, 2736 S.W. Seventh Ave., Miami 36.

Hawaii: Honolulu, Jan. 14-17. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu.

Idaho: Boise, Jan. 15. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg., Boise.

Indiana: Indianapolis, April 25-27. Sec., Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

Kentucky: Louisville, March 25-27. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville 2.

Maine: Portland, March 12-13. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

Massachusetts: Boston, March 12-15. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston.

Michigan:* Detroit, March 26-28. Sec., Board of Registration in Medicine. Dr J. E. McIntyre, 100 W. Allegan St., Lansing 8.

Montana: Helena, April 1-3. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

Nevada: Carson City, Feb. 4. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Jersey: Trenton, June 18-19. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico:* Santa Fe, April 8-9. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

New York: Jan. 28-31. Sec., Dr. Jacob L. Lochner, Education Bldg., Albany.

North Carolina: *Reciprocity.* Raleigh, Jan. 16. Sec., Dr. Ivan Proctor, Raleigh.

Ohio: *Examination.* Columbus. March 19-22. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma:* Oklahoma City, March 23. Sec., Dr. J. D. Osborn Jr., Frederick.

Oregon:* Jan. 23-26. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland 4.

Pennsylvania: Harrisburg, January. Act. Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

South Dakota:* Pierre, Jan. 15-16. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

Texas: Austin, March 27-29. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

Vermont: Burlington, March or April 1946. Sec., Dr. F. J. Lawliss, Richford.

Washington:* Seattle, Jan. 14-16. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Connecticut: Feb. 9. Address State Board of Healing Arts, 250 Church St., New Haven 10.

Florida: Gainesville, June 4. Final date for filing application is May 20. Sec. Dr. J. F. Conn, John B. Stetson University, DeLand.

Oklahoma: Oklahoma City, Jan. 21. Sec., Dr. J. D. Osborn Jr., Frederick.

Oregon: Portland, March 2. Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.

Rhode Island: Providence, Feb. 13. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Gas Bacillus Infection of Uterus Treated with Penicillin. G. S. Hudson and M. P. Rucker.—p. 452.
Ovarian Pregnancy. J. B. Ballina and N. E. Chiodi.—p. 456.

Estrogen-Progesterone Therapy in Habitual Abortion.—Vaux and Rakoff used estrogen and progesterone in the treatment of habitual abortion. Twenty-four women had gone through a total of eighty previous pregnancies from which there had resulted only 7 living babies. There had been fifty-two abortions, eighteen miscarriages, two stillbirths and one premature live birth in which the infant did not survive. More than half of these patients had no difficulty in becoming pregnant; the others had diminished or poor fertility. None of these patients had pelvic abnormalities or systemic diseases which would influence abortion. Two patients had Rh incompatibilities (Rh-negative wife and Rh-positive husband). One of these delivered a normal living baby and the others aborted; in neither case did Rh antibodies develop. Examination of the endometrium obtained by biopsy or curettage was available in 11 cases before the present pregnancy. Good secretory function was noted in 7 cases, impaired secretory function in 2 and an interval endometrium in 2. Urine hormone assays were made in 15 cases prior to the onset of pregnancy. Urine gonadotropin assays made at the midcycle were normal in 13 of these. Urine estrogens were diminished in two thirds, while pregnandiol values were low or absent in over half. Hormone assays consisting of urine pregnandiol determinations, serum estrogens and serum gonadotropins were made early in pregnancy in 19 cases. In almost all of the cases one or more additional assays were made and in 3 cases monthly assays were done. On the initial assay all except 1 showed normal serum gonadotropins, but serum estrogens and pregnandiol were diminished in more than three fourths of the patients. In 13 of the 19 patients both estrogen and pregnandiol were diminished. These findings indicate a deficiency of the corpus luteum during the early weeks of gestation and an inadequacy of the placenta to take over its functions. Many of these patients had been unsuccessfully treated in previous pregnancies with progesterone, thyroid and vitamin E. During the present pregnancy all patients were treated by the injection of progesterone 10 mg. and alpha-estradiol benzoate 10,000 rat units given together two or three times weekly. This treatment was generally continued to the period of viability or later. There were 15 full term live births with 1 neonatal death; 3 premature live births with survival of 2; 2 miscarriages, and 4 abortions.

Bilateral Polycystic Ovaries.—Stein lists menstrual irregularity featuring amenorrhea, a history of sterility, the masculine type of hirsutism and, less consistently, retarded breast development and obesity as characteristic manifestations of bilateral polycystic ovaries. In 53 patients with bilateral polycystic ovaries diagnosis was made by the presence of a typical clinical syndrome and was substantiated by gynecography (pneumoperitoneum). Endocrine and other medical therapy proved valueless. Surgical treatment in the form of bilateral ovarian wedge resection and suture has proved to be a satisfactory treatment. All of the 53 patients were treated surgically. Seventeen married patients and 3 of the single patients who subsequently married (a total of 20) became pregnant after operation, resulting in 26 pregnancies and 28 babies. Four of the women were pregnant twice, one three times, and there were two sets of twins. Periodic checkup postoperatively revealed that there were no recurrences of bilateral polycystic ovaries. Three single women who had febrile and painful postoperative courses developed a unilateral ovarian cyst with adhesions. The author recommends that bilateral polycystic ovaries associated with amenorrhea, sterility and/or hirsutism be treated by bilateral ovarian wedge resection.

Maps of Diseases.—According to Jarcho, Mercator projection maps have limitations which are of importance in world maps of tropical diseases. One of the chief disadvantages is that, since the arctic and antarctic regions are exaggerated, the equatorial zones appear disproportionately small. Territories which are of equal size on a Mercator map are not necessarily equal in area. On Mercator's projection Dutch Borneo and Iceland seem to be approximately equal in size. Actually Dutch Borneo (208,000 square miles) is more than five times as large as Iceland (39,700 square miles). For world maps intended to depict the size of areas in which a disease prevails, the Mercator projection should be supplanted by projections exhibiting the "equal area" property. Equal area projections, such as Mollweide's projection, the sinusoidal projection and Goode's homolosine projection, all possess the equal area property. The azimuthal equidistant projection is a cartographic tool which shows the distance between one focal point and all other points on the earth's surface. This projection is suitable for world maps of diseases which have a relatively small and continuous realm of distribution. Examples of such diseases are cholera, tsutsugamushi fever, Russian spring-summer encephalitis, filariasis caused by Wuchereria malayi and fièvre boutonneuse. Every map drawn on the azimuthal equidistant projection is centered on a definite point, usually a city. The text is accompanied by maps drawn according to different projections to illustrate certain points stressed by the author.

Pleural Shock and Cerebral Embolism.—According to Andosca and Foley, pleural puncture employed either in pneumothorax therapy, in aspiration of an empyema cavity or in exploratory thoracocentesis may result in signs and symptoms which have been diagnosed either as pleural shock or as cerebral embolism. The confusion which exists between the two diagnoses gives a false impression concerning the seriousness of the complication. Pleural shock is rare and may occur in excitable and neurotic patients, but the symptom complex of cyanosis, changes in respiration and circulation, convulsions, ocular disturbances, loss of consciousness, aphasia, paralysis and sometimes death, occurring during pleural puncture, is definitely due to cerebral embolism. The treatment consists in lowering the patient's head and giving cardiac stimulants. The prognosis in cerebral embolism depends on the amount of air entering the blood stream and the region of the brain most seriously involved. The authors have encountered 12 cases with 3 fatalities in a series of 90,120 pleural punctures at the Boston Sanatorium. One of the fatal cases was attributed to procaine hydrochloride poisoning. Procaine hydrochloride in a 1 per cent solution should be employed only for the initial pneumothorax treatment and not for the subsequent refills.

Aero-Otitis Media.—Wright thinks that the adenoid and lymphoid tissue in the epipharynx is the important causal agent in aero-otitis media. This tissue is easily inflamed by upper respiratory disease and accounts for the high incidence of aero-otitis media in the group between 18 and 27 years which he studied. In older age groups, in which there is an atrophy of lymphoid tissue, there may be a different picture. The pain may be moderate or so severe as to cause unconsciousness and shock. There may be nausea, vomiting and dizziness. The pain is usually deep in the ear but may be in front of the ear or over the mastoid region. The pain, even though severe for a time, is of short duration and is followed by symptoms of stuffiness and loss of hearing. The acute aero-otitis media does not demand much in the way of relief. The pain has almost invariably disappeared on arrival at the clinic. Inflation usually helps after some days have elapsed and the hearing loss and the stuffiness persist. Since the adenoid tissue seems to be the important pathologic factor in the production of aero-otitis media, the prophylactic treatment is the elimination of adenoid tissue. If a large mass of adenoid tissue is found, it is removed surgically. If the adenoid tissue is around the tubes and in the vault, which is its usual location, it is treated by irradiation in fractional doses. Treatment with x-rays or radium should give good results, such as have already been demonstrated in children in the treatment of deafness which exists on the same pathologic basis. The author has observed 39 cases of purulent otitis media occurring as a complication of aero-otitis media.

Rupture of Tympanic Membrane Due to Blast.—Cantor states that rupture of the tympanic membrane can be explained without a negative pressure being present. The damage, such as the removal of the ossicular chain, cannot be explained by a negative pressure of even 15 pounds to the square inch but can be explained by his positive pressure hypothesis. The pathway of the blast is through the eustachian tube and not through the external auditory canal. Unilateral rupture of the tympanic membrane is due to the occlusion of the eustachian tube on the unruptured side. Pathologic conditions of the nose may be responsible for the rupture of the tympanic membrane. Internal ear damage can best be explained by this hypothesis. To afford the maximum degree of protection, the lateral surface of the drum should be protected from the direct force of the blast; the person should assume a crouching position, thereby forcing the abdominal viscera against the diaphragm and expelling the maximum amount of air from the body cavities; and the mouth should be open and the nose clear so that the residual air compressed in the body cavities is not forced into the eustachian tubes and the middle ears.

Ophthalmodynamometry. F. L. P. Koch.—p. 234.

Vitamin C Saturation and Senile Cataract.—Rados performed the saturation test for vitamin C on 200 patients with cataract. Of these patients 135 showed an excretion level approximating that found in normal subjects living on an adequate mixed diet. The remaining 65 showed a low level; in 35 the deficiency was mild, but in 30 it was more severe. The author concludes that there is not sufficient evidence to indicate that vitamin C deficiency contributes to the formation of cataract. Transparency of the lens is not dependent on the vitamin C saturation of the body, since the large number of senile cataracts associated with a normal saturation level would contradict such an assumption. The vitamin C deficiency of some of the patients with cataract seems to be the natural result of the vitamin C deficiency of old age.

Paranasal Sinuses S Salinger —p 212

Effects of Gun Blasts on Hearing.—An initial survey of 45 gunnery instructors was carried out by Machle to establish the characteristics of the hearing loss that had occurred in armored personnel frequently exposed to blasts of 37 and 75 mm. guns. Experimental studies under controlled conditions were carried out on 12 subjects. Repeated audiometric tests were made for four days prior to exposure. A base line was thus established The better ear was then used as the test ear. During exposure the control ear was protected by a soft rubber plug carefully fitted into the canal and a sponge rubber pad covering the external ear, over all of which a heavy cloth helmet was firmly held by a rubber band The men were exposed to gun blasts as follows: 8 to that of the 75 mm. gun, 3 to that of the 37 mm. gun and 3 to that of the 0.30 caliber machine gun They were placed at measured distances at right angles to the barrel of the gun at the level of the muzzle; with the 75 and 37 mm guns, the subjects were at a distance of 8 feet (2.4 meters); with the 0 30 caliber machine gun, at a distance of 6 feet (about 2 meters). Audiometric examinations were begun within five minutes after exposure and were repeated at intervals of two, four and twenty-four hours, with the twenty-four hour pattern being used as the base line for the next exposure record At the conclusion of the overall period of exposure, recovery was observed by means of daily audiograms. It was found that the characteristics of the hearing loss following controlled exposure to gun blast are like those of deafness from sustained high noise levels Acoustic injury and loss are common in gunnery instructors, artillerists and others, potentially serious partial deafness may be expected to occur in significant numbers of military personnel. With repeated equal exposures, acoustic damage is cumulative, apparently largely because recovery from the initial traumatic response is incomplete. Partial recovery of hearing regularly occurs in the first few days after cessation of repeated daily exposures. After months of exposure, recovery to preexposure levels of acuity is doubtful; there was evidence of partial recovery in only 2 of 10 men studied

Morphologic Aspects and Genesis of Disorders of Adenohypophysis J. E. Kraus.—p 191

Experimental Endocarditis in Rats.—Clawson attempted to produce acute rheumatic and bacterial endocarditis in rats. Valvular lesions closely simulating acute rheumatic endocarditis anatomically could be produced in a high percentage of rats by injecting either Streptococcus viridans or Streptococcus hemolyticus into the blood stream. Some of the rheumatic-like lesions showed a degree of healing resembling the early healing observed in human rheumatic valvulitis. Lesions similar to human bacterial endocarditis were produced on the same valve or on separate valves in association with the rheumatic-like vegetations, or the bacterial vegetations occurred independently. These rheumatic-like and bacterial lesions were produced only when the bacterial organisms were in the blood stream Endocarditis failed to develop following the injection of other proteins: Dick toxin, rabbit and horse serums, egg albumin and an extract of Streptococcus viridans. Agglutinins in the blood stream apparently favor the development of valvulitis. Hypersensitiveness (allergy), immediate (anaphylactic) or delayed (bacterial), does not appear to be a factor in the genesis of the endocarditis except possibly in the bacterial form of endocarditis, in which the delayed type of hypersensitiveness may have been an influencing factor. These experiments support the theory that acute rheumatic endocarditis and bacterial endocarditis are etiologically similar but differ in degree of manifestation and that they occur as a response to a direct valvular infection with the bacterial cells.

*Rat Bite Fever Due to Streptobacillus Moniliformis Treated with Penicillin: Case R A. Weber and C B Favour —p 132

Penicillin in Rat Bite Fever.—According to Weber and Favour, Streptobacillus moniliformis infections subsequent to rat bite have reacted unpredictably to arsenicals, aurothiomalate and sulfonamides. They may cause months to years of severe disability and may terminate fatally. Weber and Favour report a case of rat bite fever due to Streptobacillus moniliformis in which the organism isolated from the patient's blood was found to be inhibited by as little as 0.001 unit of penicillin per cubic centimeter in mediums which normally supported luxuriant growth. Intramuscular penicillin therapy was associated with prompt recovery. The patient has remained well one year later

What is pH? Explanation of Various Measures of Acidity Employed in Gastroenterology. F. Hollander —p 497

Hypertrophic Gastritis Simulating Gastric Carcinoma.—Pollard and Cooper of the University Hospital of Ann Arbor, Mich., during the past four years observed 8 patients whose gastric roentgenograms revealed a filling defect which strongly suggested a neoplasm. All were men between the ages of 22 and 65. In all but 2 cases the diagnosis of localized hypertrophic gastritis was established with reasonable certainty by gastroscopy. This diagnosis and the absence of neoplasm were confirmed in 7 of the 8 cases by laparotomy and in 6 of the cases by microscopic examination of removed tissue. Since early diagnosis and treatment are essential in the management of gastric neoplasm and operation may be contraindicated in cases of hypertrophic gastritis, it seems important that all these cases be subjected to gastroscopy before surgery is undertaken. It is wise not to depend on a trial of conservative therapy to establish the diagnosis.

Personality Disintegration Following Nitrous Oxide Anesthesia.—Fletcher studied 29 cases of personality disintegration following the use of nitrous oxide. Nervous and mental residuals following nitrous oxide anesthesia persisted for many years in 1 case. Another case illustrated that a small quantity of nitrous oxide given repeatedly may have a cumulative effect and lead to severe distintegration of the personality. A single administration of nitrous oxide, apparently unaccompanied by respiratory difficulties, may result in serious nervous and mental impairment with personality changes. One of the patients, who was nervously unstable, suffered from mental impairment following nitrous oxide anesthesia. It is reasonable to believe that such inherent constitutional weakness would be enhanced by nitrous oxide. The author regards anoxemia as the etiologic factor of the disturbances caused by nitrous oxide. The problem of anesthesia and anoxia may be related to problem children in school. A general anesthetic, frequently nitrous oxide, is employed for the removal of tonsils, adenoids and teeth of children of all ages. Many perplexing problems of the school room may possibly be explained on this basis.

Mercuhydrin and Mercupurin.—Modell and his associates compare the diuretic potency and irritant properties of mercuhydrin with mercurophylline or mercupurin. Mercuhydrin is supplied in the form of a solution of the sodium salt and each cubic centimeter contains 88 mg. of the compound representing 39 mg. of mercury in organic combination with 48 mg. of theophylline. The authors used mercuhydrin in 92 patients, and in 43 of these quantitative comparisons were made with mercupurin. The patients were selected from 1,500 ambulant patients in attendance at the cardiac clinics. All had organic heart disease with advanced congestive failure. All the common varieties of heart disease were represented, namely arteriosclerotic, hypertensive, rheumatic, syphilitic and hyperthyroid. There were approximately equal numbers of the two sexes in ages from 24 to 78 years. In the dosage range of 1 and 2 cc. the diuretic responses to mercuhydrin and mercupurin by intramuscular and intravenous administration are indistinguishable. Neither of the two agents produces renal injury, as shown by urine examinations and blood nonprotein nitrogen values after weekly injections for periods of three months. A comparison with a "blind test" method shows that mercuhydrin is less irritant than mercupurin by intramuscular injection. Hypersensitivity to either of these agents may not necessarily extend to the other.

Poliomyelitis and Acute Gastrointestinal Upsets.—Kovar observed an acute clinical condition with symptoms and signs similar to those of the preparalytic stage of acute anterior poliomyelitis. The condition made its appearance during the epidemic periods of poliomyelitis in Nebraska and in the years of severe drought and economic depression. There were fever, drowsiness, headache, pain and slight rigidity of the neck, pain and some rigidity of the spine and pain in the legs. The spinal fluid was normal. The author concluded that these cases were gastrointestinal in origin and that the preparalytic symptoms of poliomyelitis were the result of avitaminosis B. He describes 3 typical cases and stresses that acute toxic gastrointestinal upsets are capable of producing symptoms similar to those of the preparalytic stage of poliomyelitis due basically to avitaminosis B and a subclinical acute beriberi. All patients with simple acute gastrointestinal conditions encountered during epidemic periods of poliomyelitis should be given large doses of vitamin B. Vitamin B is also indicated as an adjunct to treatment in all acute debilitating diseases and especially in diarrheas. It is suggested that, if tonsils are to be removed during the poliomyelitis season, high vitamin B intake be insured both before and after operation. Many so-called abortive cases of poliomyelitis may be in reality an acute gastrointestinal condition characterized by symptoms of avitaminosis B. Vitamin B plays an important part in the etiology of poliomyelitis, and the nutritional aspect of poliomyelitis should be thoroughly investigated.

Rabbit Serum in Experimental Tsutsugamushi Disease.—Topping thinks that, from a clinical standpoint, tsutsugamushi disease might lend itself more readily to therapy and even to prophylaxis with an immune serum than Rocky Mountain spotted fever. With the eschar as an early diagnostic feature, immune serum or some other therapeutic agent could be given earlier and with greater benefit. It has been demonstrated that rabbits suitably inoculated with live antigen from a strain of tsutsugamushi disease develop protective antibodies. A second series of inoculations apparently raises the protective antibody titer. These antibodies can be passively transferred to mice previously infected with lethal doses of yolk sac material from the homologous strain. Death can be prevented in the infected mice, when treated with the serum, after an interval of seventy-two to one hundred and sixty-eight hours from the time of infection. In these tests it appeared that the larger dose was more effective than the smaller.

Effects of Intravenous Fluids on Bleeding and Clotting Time.—Three patients on whom vaginal plastic operations had been done at a Galveston hospital developed delayed hemorrhage after receiving over 1,500 cc. of intravenous fluid during and after the operation. Each recovered from hemorrhage and shock promptly without transfusion, packing, blood coagulants or other measures. Studies were made by Baxter on patients who were being prepared for operation and on women after delivery. Three groups of 20 and two groups of 15 patients were studied. The bleeding and clotting time, pulse and blood pressure were taken prior to starting fluids and after each thousand cubic centimeters given. The urinary output was likewise charted. The bleeding time was taken by making a small incision in the lobe of the ear and blotting every thirty seconds with filter paper. The clotting time was taken by the Duke method, placing a drop of blood on a slide and drawing a pin through it every thirty seconds until two or three successive strings of fibrin formed. It was found that isotonic solution of sodium chloride in large quantities (5,000 cc.) caused an increase in the bleeding and clotting time. Five per cent dextrose in isotonic solution of sodium chloride, 5 per cent dextrose in distilled water and 10 per cent dextrose in distilled water decreased the bleeding and clotting time. Fifty per cent dextrose caused no change. The blood pressures varied. There was an average rise of 19 points systolic pressure with isotonic solution of sodium chloride; 13 points systolic, 2 points diastolic with 5 per cent dextrose in isotonic solution of sodium chloride; and 23 points systolic, 4 points diastolic with 10 per cent dextrose. The pulse rate varied usually not over 10 points but occasionally rose 20 points. The urinary output during infusion was as follows: isotonic solution of sodium chloride, 1,115 cc.; 5 per cent dextrose in isotonic solution of sodium chloride, 2,083 cc.; 5 per cent dextrose in distilled water, 4,438 cc.; 10 per cent dextrose in distilled water, 5,360 cc.; highest, 5,800 cc. Fifty per cent dextrose resulted in normal output.

Influence of White Fraction from Reticulogen on Leukocyte Equilibrium.—Berry and his associates observed that leukopenia was prevalent in the malnourished patients who visited their clinic and that the leukopenic patients frequently complained of ulcers in the oral mucous membranes, and some of these persons had bouts of pyoderma. Intravenous injection of a substance obtained in fractionating reticulogen in doses ranging from 20 to 60 mg. was followed by an increase in concentration of leukocytes in the peripheral blood in 12 of 14 patients. Of the 2 that showed no such response, 1 had severe food sensitivities and daily urticarial reactions, the other a profound agranulocytic leukopenia of unknown etiology. The increase in total white blood cells in the 12 malnourished persons was found to be due almost entirely to an increase in neutrophils. At or near the peak of the rise there was a left shift in the Arneth nuclear index. These observations, combined with the fact that essentially constant numbers of lymphocytes, monocytes and erythrocytes were found throughout the test period, were interpreted as reflecting a direct bone marrow delivery of the granulocytic cells.

Choline in Disease of Liver.—Herrmann and Rockwell report 32 cases of hepatic cirrhosis studied in the John Sealy Hospital in Galveston, Texas. A low serum albumin seemed to be the most reliable single sign of liver disease. Six clinical cases are presented in detail. Liver damage in 4 of the patients proved reversible. The enlarged livers were caused by alcoholic dietary deficiency and probably fatty metamorphosis; 2 of the patients responded to high protein diets supplemented with casein hydrolysates and brewers' yeast of high choline content. Four patients likewise responded conspicuously to the addition of choline chloride to the diet. Two cases of chronic cirrhosis of the liver with shrunken hobnailed livers and ascites failed to show response to choline chloride administration. Two patients with chronically engorged and anoxic livers of congestive heart failure, with possibly some fatty changes, showed striking reduction in the liver and general improvement following the administration of choline chloride in addition to other supportive drugs. The choline chloride may not only act as a lipotrophic substance in these cases but may also contribute to improved myocardial efficiency. Experimental studies on the effects of choline on the cholesterol content of the aorta, heart and liver of aged hens suggests that choline mobilizes cholesterol from the aorta and changes it to phospholipids. Enlarged fatty livers due to anemia and toxemia, as well as alcohol, diabetes, congestive failure or carbon tetrachloride poisoning, are likely to respond to choline, methionine, betaine, inositol or lipocaic.

Rheumatic Fever in Young Adults.—Kimbro discusses the clinical and laboratory features of 100 cases of rheumatic fever in army personnel. Twenty-nine of this group gave a previous history of rheumatic fever in childhood. Pain in a joint of the lower extremity was the initial symptom in the majority of the cases. In 84 cases joint pains were migratory, while in the remaining 16 they were confined to one joint. As a result of the extreme mildness of the arthralgia, the patient was frequently sent to the hospital with the diagnosis of flat feet or sprained ankle and only electrocardiographic abnormalities and the persistence of the elevated sedimentation rate led to the diagnosis of active rheumatic fever. As soon as the diagnosis is made, sodium salicylate should be started in doses that will give a blood salicyl level of at least 375 micrograms per cubic centimeter. The dose necessary to maintain this blood level was 40 grains (2.65 Gm.) given every six hours orally. If the oral dosage does not maintain an adequate blood salicyl level, intravenous administration of salicylate is advisable in doses of 10 Gm. per thousand cubic centimeters of isotonic solution of sodium chloride as outlined by Coburn. Salicylates were given on the average for 47.9 days; the longest period was 157 days. The average daily dosage was 132 grains (8.5 Gm.). The response was good in 71 cases. The analgesic, antipyretic and antiphlogistic action of salicylates was demonstrated. Response was moderate with 15 and poor in 9. Sixty-two of the 93 patients who have been observed for a sufficient length of time were returned to full military duty. Sixteen showed evidence of cardiac damage. Seven patients are being held for further observation because of residual heart disease. Four patients with the diagnosis of rheumatic fever proved to have rheumatoid arthritis and were discharged. Treatment with salicylates without the addition of sodium bicarbonate is indicated in rheumatic fever. Sulfonamide prophylaxis is indicated in all rheumatic fever subjects during the winter months.

Penicillin and Chemotherapy in Gonorrheal Urethritis.—Between Dec. 15, 1944 and July 1, 1945 Alley treated 159 cases of acute gonorrheal urethritis. The criteria of diagnosis were the presence of a purulent urethral discharge and demonstration of Neisseria gonorrheae in smears. The first 54 consecutive cases were treated with penicillin alone initially, and in refractory cases this was followed by additional penicillin, sulfathiazole or both. A combination of penicillin and sulfathiazole was employed in 105 of the cases, and the recovery rate in these was 100 per cent. The author concludes that a combination of penicillin and chemotherapy is the rational therapy for acute gonorrheal urethritis for the following reasons: 1. There appears to be a synergistic action between the two drugs when used concomitantly. 2. Both penicillin resistant and chemoresistant cases are provided for under this regimen.

Interference of Penicillin in Determination of Albumin in Urine.—Perlstein and his associates gave intravenous injections of from 300,000 to 400,000 units of penicillin to rabbits weighing from 1,500 to 2,000 Gm. Albumin tests were performed on urine collected from these animals both prior to and after injection of penicillin. The qualitative albumin tests were all negative for albumin before treatment. Severe anuria was noted during the first twenty-four hours following treatment. This condition diminished progressively during the second and third twenty-four hour periods. The output of urine returned to normal during the fourth twenty-four hour period. The samples of urine collected during the first and second twenty-four hour periods following treatment gave triple and quadruple albumin reactions. The samples collected during the fourth twenty-four hour period were negative. The original assumption that an albuminuria had been induced was not found valid. The pseudopositive albumin test appears to be due entirely to the penicillin in the urine. It was later found that on the addition of 25 per cent by volume of acetone or ethyl alcohol to the tube containing 5 cc. of urine no precipitation will occur in the presence of penicillin with the addition of the reagent. By following this precaution, the pseudoreaction can be avoided and a true albumin test can be performed. This test has a limitation in that, beyond a concentration of from 10 to 13 mg. of penicillin in the urine, the acetone or alcohol will suppress but not eliminate the interference of penicillin in the albumin test.

The One Eyed Worker.—Minton studied 100 men and women who had lost an eye. The greatest number of eye injuries occurs in the mining industries and the metal and engineering industries. After the excision of an eye the patient takes time to adjust himself to the new visual conditions. Errors in the estimation of distances are made by all during the first few weeks. Gradually the judgment of distances becomes more accurate. The ability to estimate depth perception is also gradually regained. Young persons adjust themselves to the new visual conditions much more quickly than older persons. Simple exercises combined with playing ball have greatly accelerated the process of visual readaptation. It would be helpful if rehabilitation centers were established at eye hospitals. The eye injuries of this war will add a large number of men to the mass of one eyed workers. Many of these men will be anxious to return to their prewar employment. The men should be advised against returning to work which involves chipping, hammering or the drilling of metal. They should not be employed in underground work in the mining industry. Although these men and women are fit for most jobs, the safety of the good eye should be the first consideration.

Rat Bite Fever Due to Cat Bite.—Swyer reports a case of rat bite fever in a man aged 36 who had been bitten on the finger by a kitten. Many of the manifestations conformed to the classic picture, but there were also some aberrant features, such as the occurrence of severe myositis, repeated relapse after arsenotherapy and apparent cure by means of penicillin. Neither *rat bite nor cat bite fever* is a satisfactory term, because these two animals are not the only vectors of the disease. The term sodoku is no better, because it means rat poison. The author thinks that spirillosis is the most acceptable term.

Prefrontal Leukotomy.—In the 100 cases in which Berliner and his associates performed prefrontal leukotomy the criterion for selection was the presence of "mental tension." This concept of mental tension may be described as a persistent emotional charge which is always of an unpleasant quality, invariably distressing and sometimes intolerable to the patient. Its presence is shown by irritability, rage, fear or other forms of emotional excitation, insomnia, restlessness, aggressiveness, destructiveness or impulsive behavor. Eighty-eight of the 100 cases presented schizophrenia, the remainder melancholia, obsessional states, epilepsy or hallucinosis. The authors used the operative technic described by Freeman and Watts. Urinary incontinence was present in many cases for periods varying from a few days to a few weeks, but it never lasted more than five weeks. Fecal incontinence was observed in a few instances during the postoperative confusional stage. Epileptiform fits occurred in 2 cases but did not continue. All signs of postoperative organic disturbance of memory, orientation or other intellectual functions were transient except in 1 patient. Recovery indicates ability to leave the hospital, live at home under normal conditions and resume some form of useful employment, not necessarily up to former standards. Twenty-nine patients can be regarded as recovered. Sixteen are much improved; that is, they do useful work in the hospital. Twenty-five are improved; many of these who were serious nursing problems before operation now take part in occupational and recreational therapy or do simple work in the hospital or on the farm. Fourteen patients have improved slightly, and this has usually meant the loss of certain troublesome features of their illness such as violent or impulsive behavior, faulty habits or destructiveness; other symptoms persist. Twelve patients may be regarded as unchanged and remain in approximately their preoperative state. Four of the 100 patients died after the operation. The impression of other workers that the best results are achieved in cases showing signs of "mental tension" is supported by this series.

Toxemia of Gas Gangrene.—MacFarlane and MacLennan suggest that there are two different substrates in the muscle, the trypsin soluble, toxin insoluble protein of the fiber and the toxin soluble, trypsin insoluble framework on which the structural integrity of the muscle depends. The latter substance, whether it is derived from the sarcolemma or from the perimysial connective tissue, is presumably formed of collagen. This supposition was supported by the finding that toxin would lyse finely teased collagen fibers derived from human tendon even in dilutions up to 1 in 64. A "collagenase" has been identified in Clostridium welchi toxin. The possibility that the general toxemia of gas gangrene is not due to alpha toxin but to the products of tissue breakdown has been studied, and evidence in favor of this theory has been obtained. Even the largest doses of antitoxin will not alleviate the toxemia of gas gangrene as long as the local destruction of muscle is proceeding. A possible relationship has been noted between the toxemia of gas gangrene and that seen in other forms of shock.

Staphylococcic Fasciitis and Penicillin Therapy.—Starr found that in a group of battle casualties soft tissue sinuses persisted. There were often multiple openings in the skin from which small amounts of seropus were discharged daily. This pus yielded hemolytic Staphylococcus aureus. For a time penicillin therapy diminished the discharge and appeared to control the infection, but recrudescence was constant. All patients had been subjected to repeated surgical intervention. This condition is a subacute staphylococcic infection of fascioaponeurotic planes with progressive necrosis of the tissue and is analogous to subacute staphylococcic infection of bone. Starr describes 6 cases of this type and the successful management of 5 of them. Surgical intervention is not undertaken unless the hemoglobin value, red blood cell count and hematocrit estimations are normal. Preoperative instillation of penicillin solution (2,500 Oxford units per cubic centimeter) is employed for three to seven days until the infection is controlled and the culture material is negative for staphylococci. At operation a wide exposure is necessary, and all sinuses are made to communicate with the main cavity. When the skin and fat are undermined, the fascia is exposed. The fat is often hard and edematous, and primary healing in these cases is difficult to secure. The fascia has a dead white or mottled appearance and is thickened and hard. It is in fact a "fascial sequestrum." Its eradication is essential. The resulting cavity is often very large, but its wall is not infrequently composed of muscle bellies and heals rapidly. Tubes are inserted into the cavity for postoperative local penicillin therapy. This is required for about seven days. No buried sutures are inserted except for the ligation of large vessels. The wound is closed with interrupted stainless steel wire sutures, which are left in place for two weeks.

Muscle Hernia.—Small defects in the fascial sheath usually cause aching pain and cramping. Sometimes, however, these defects occur without symptoms. The muscles of the anterior tibial group, particularly the tibialis anterior, are most frequently involved. In 4 of the 6 cases described in this paper the anterior tibial group was involved, the anterior aspect of the forearm being the site of the defect in the remaining 2. Though the hernia is often caused by an injury, more frequently it is related to the less acute but more prolonged trauma of excessive walking. These cases show two unusual responses to mild trauma: (1) failure of a small defect in the deep fascia to heal and (2) muscular dysfunction with pain. It is well known that even major defects in the deep fascia almost invariably heal, as is evidenced by the reforming of the fascia lata after the removal of large strips. There seems to be no doubt that the failure of the fascia to unite causes disorder of muscular function with consequent aching pain. McMaster treated 8 cases by surgical repair but was not enthusiastic about the results. Attempts have been made to close the fascial defect by injections of sodium morrhuate, with improvement in symptoms for a few months only. Kelly made no attempt to treat his patients.

Anesthesia in Operations for Patent Ductus Arteriosus.—In his experience, which has been limited to twenty-one ligations, Gillies says that anesthesia for the uninfected and younger subjects presented little difficulty. It is familiar knowledge that children tolerate thoracotomy better than older subjects. Patients with infection were in a critical condition during operation. Adequate oxygenation may be difficult because of patchy areas of consolidation in the lungs as a result of emboli from the infected vessels. Although the management of the anesthesia for this operation is not essentially difficult, it must be of such quality that the surgeon receives maximum assistance in his delicate manipulations. The quietest respiration consistent with good oxygenation must be maintained. A high oxygen content helps oxygenation by continuous diffusion into the alveoli when respiratory excursion is reduced. Quiet breathing will also minimize mediastinal movement. Cyclopropane has been employed almost entirely in this series, with satisfactory results. The use of a tracheal tube is not essential but is a comforting safeguard against mechanical obstruction of the airway. Complete deflation, especially under prolonged pack or retractor pressure, sometimes causes difficulty in reexpanding the lung. Jones interrupts the operation in order that the anesthetist may reinflate the lung for a few seconds every ten minutes. This is a definite aid in facilitating the final reexpansion at the end of the operation and of mitigating postoperative pulmonary complications.

Carbon Dioxide Content of Plasma.—Binet and Strumza studied the total carbon dioxide content of the plasma in dogs which were anesthesized by chloral and in which shock was produced by repeated injections of histamine. First a rapid and later a slower but progressive decrease in blood alkali was demonstrated. A fall of alkali to 50 per cent of its initial value was observed within one hour. As a measure of blood alkali, analysis for total carbon dioxide was made and a decrease of the carbon dioxide to 14.7 and to 12.7 per cent by volume was demonstrated within seven to seven and a half hours after shock was induced. In additional experiments, moderate and extensive hemorrhages were produced in anesthesized dogs. Isotonic solution of sodium chloride was administered to those dogs which had lost three fifths of their total blood. In the dogs subjected to hemorrhage, the carbon dioxide varied from 32 to 13 per cent by volume and the lowest value was observed within seven hours after the hemorrhage. In spite of the administration of isotonic solution of sodium chloride, the decrease of the carbon dioxide content and of the alkali in the blood continued in the dogs subjected to profuse hemorrhage. Good initial results were obtained by adding 4 Gm. of sodium bicarbonate per thousand cubic centimeters to the isotonic solution of sodium chloride. Repeated bicarbonate injections were required to prevent a later fall of the carbon dioxide content and to maintain a normal blood alkali as long as the posthemorrhagic anemia was not attenuated.

*Problem of Malignancy of Granulosa Cell Tumors. E. Glatthaar.—p. 304.
New Method for Revival of Asphyctic Newborn Infants. N. Erez. —p. 313

Malignancy of Granulosa Cell Tumors.—Glatthaar describes a case of granulosa cell tumor of the ovary which was clinically malignant but microscopically had the structure of a benign granulosa cell tumor. Laparotomy disclosed an enlarged uterus and bilateral, nodulated, apparently malignant tumors of the ovaries, which already had caused extensive metastases. The tumors and metastases were extirpated and the uterus was amputated. Microscopic examination revealed that the bilateral ovarian tumors were granulosa cell tumors. Highly differentiated tissues were interspersed with some of a more diffuse structure. The metastases showed essentially the same structure. The clinical aspects of this case were definitely malignant but the microscopic structure was that of a benign granulosa cell tumor. Since the microscopic appearances are not reliable in cases of granulosa cell tumors, the therapy must be *governed by the clinical features.*

*Deteriorating Therapeutic Effect of Sulfathiazole in Gonorrhea. G. Seeberg.—p. 361.
*Local Treatment of Gonorrhea with Sulfathiazole: Clinical Investigation. G. Seeberg.—p. 380.

Sulfathiazole Resistance in Gonorrhea.—Seeberg studied uniform material from outpatient wards comprising 3,428 patients, 2,930 of whom were men and 498 women. They all had an uncomplicated form of gonorrhea for which they had received one period of intensive sulfathiazole treatment. The recurrence frequency among men rose from 15 per cent at the beginning of 1941 to 70 to 80 per cent at the end of 1943 and remained at the latter figure during the first months of 1944. Among the women the incidence of recurrence rose from 30 per cent at the beginning of 1943 to 70 per cent at the close of the same year. The recurrence frequency was about the same for those infected in Stockholm and for patients infected outside the city. Recurrences were diagnosed by culture and by microscopic examination of direct specimens as late as the fourth week in men and the eighth week in women. This observation shows the necessity for an effective control period following the treatment. The explanation for the deteriorating results reflected in the rising recurrence frequency seems to lie in the fact that an increasing number of strains of gonococci have become chemoresistant.

Local Sulfathiazole Therapy of Gonorrhea.—Seeberg reports the results of treatment of 86 gonorrhea patients with sulfathiazole by local application. Sixty-four of the patients were men and 22 were women. Ten cc. of 15 per cent microcrystalline sulfathiazole suspended in water was injected into the urethra of the men. The patient retained this suspension for ten minutes. The treatment was repeated six times daily for seven days. One sulfathiazole suppository was introduced into the urethra and one into the rectum of the women six times daily, and one suppository was inserted in the cervical canal twice a day for seven days. With local treatment only, gonorrhea was cured in 8 of 30 men, while there were no cures among the 9 women treated by the local application. With combined local and oral treatment, gonorrhea was cured in 12 of 34 men and 5 of 13 women. In the majority of the cases local application of sulfathiazole had no therapeutic effect. The reason for this is believed to be an increased chemoresistance of the gonococci.

Book Notices

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1944, with the Comments That Have Appeared in The Journal. Cloth. Price, $1. Pp. 238, with 50 illustrations. Chicago: American Medical Association, 1945.

This volume was originally designed as a complement to another publication of the Council, New and Nonofficial Remedies, the latter designed to list and describe preparations found acceptable by the Council, the former to explain why the Council found certain preparations unacceptable. The annual reprint was also designed to contain reports of other deliberations of the Council as well as comments that appeared in THE JOURNAL. The present volume is quite unusual in that it contains not one report concerning a product found unacceptable. However, there are five reports on the omission of products from New and Nonofficial Remedies, mainly for the reason that they have outlived their usefulness, and in most cases the manufacturers have expressed their lack of desire for continued inclusion of their brands. These reports are Erysipelas Streptococcus Antitoxin and Antierysipelas Serum Omitted from New and Nonofficial Remedies; Ichthammol Preparations, Isarol, Ichthynat, Ichthyol, Omitted from New and Nonofficial Remedies, and Soluble Ichthammol Not Within the Scope of New and Nonofficial Remedies; Iodine Compounds Iodalbin and Stearodine, Iodo-Casein, Iothion and Iodostarine Omitted from New and Nonofficial Remedies; Mercuric Oxycyanide, Mercuric Salicylate and Mercuric Succinimide Omitted from New and Nonofficial Remedies, and Status of Antimeningococcic Serum and Meningococcus Antitoxin.

This volume is a veritable mine of information on subjects of general interest to the physician, pharmacist and the pharmaceutical manufacturer. The reports concern deliberations of the Council on general subjects ranging from the use of the electron microscope to the appraisal of new drugs. The report on Pathogenic Bacteria, Rickettsias and Viruses as Shown by the Electron Microscope is noteworthy as being pioneer work in this field. The report on the Current Status of Prophylaxis by Hemophilus Pertussis Vaccine was prefatory to the acceptance by the Council on various brands of pertussis vaccines and pertussis vaccine combinations. The valuable and highly informative article on Local Treatment of Thermal Cutaneous Burns reports the latest and best work in this field.

Voluntary Health Agencies: An Interpretive Study. By Selskar M. Gunn and Philip S. Platt. With a foreword by Louis I. Dublin. Under the auspices of the National Health Council. Cloth. Price, $3. Pp. 364. New York: Ronald Press Company, 1945.

This book is a study under the auspices of the National Health Council made possible by financial support from the Rockefeller Foundation.

For many years there has been a growing feeling in public health circles that too many voluntary health organizations exist and that their programs, financing and other relationships are spotty, unequal, overlapping and not well proportioned to needs in the several fields. The organization of the National Health Council itself was an effort to correct these conditions. The National Health Council was apparently premature, since the desired objectives were not obtained. This study was initiated to learn as much as possible about existing types of voluntary health agencies at the federal, state and local level and making recommendations as to how these might be strengthened, consolidated or coordinated. The directors of the study, under whose authorship the book is published, are both experienced in various phases of public health work in the United States and elsewhere. They were well fitted by experience and training to undertake such a study. With the aid of a field worker, they visited numerous communities and talked with the executives or other officers of hundreds of typical health agencies. It was impossible to talk to a representative of each of the twenty-two thousand known voluntary health agencies in the United States.

The book is a description of the problem from the standpoint of what constitutes a voluntary health agency, what its social values and functions are and where such voluntary agencies lack. Among reasons why they lack, the human factor is of tremendous importance. Recommendations are presented as to how the effectiveness of health agencies might be increased. Considerable attention is devoted to statewide and nationwide organizations. A chapter is devoted to the professional organizations, namely the American Public Health Association, the National Organization for Public Health Nursing, the American Medical Association, the American Dental Association and the National Safety Council. The description of the American Medical Association, its organization, purposes and activities is one of the few fair factual and objective presentations relating to this organization which can be found.

The remedies proposed for confusion, duplication, overlapping and gaps in the voluntary health field include close coordination beginning at the federal level with an ultimate goal of a unified health program and wide coordination of the national health agencies. An overall fund raising and coordinate body similar to the National War Fund is suggested.

Any one who has experienced the multiplicity of health agencies at federal, state and local levels and the almost innumerable "health projects" essayed by agencies whose primary objective is something other than a health program cannot help but be interested in this study. The authors have been courageous in their study and in their recommendations. If they receive the attention which they ought to receive, and anything approaching the action recommended, the entire public health movement should derive great benefits.

Nutrition and Relief Work: A Handbook for the Guidance of Relief Workers. Published by the Council of British Societies for Relief Abroad. Cloth. Price, 70 cents. Pp. 111, with illustrations. New York, London & Toronto: Oxford University Press, 1945.

This small book represents an effort on the part of certain British war relief agencies with the cooperation of British nutritionists to provide a manual on nutrition of use in relief feeding. It begins with a brief discussion of the energy requirements of various occupational activities. The functions of the vitamins essential for human nutrition and the quantities needed daily are given as well as the symptoms of vitamin deficiencies. An outline of methods for determining the nutritional adequacy of a population includes the gathering of data on food consumption and examination of the representative groups with particular reference to certain objective findings which are listed. Further practical information relating to problems met in caring for the European peoples, such as differing dietary habits, storage and handling of foodstuffs, makeshift cooking arrangements and descriptions of the different currencies and systems of measurement, is to be found in the manual. Diagrams of cooking units, large scale recipes and tables of food values add to the usefulness of the book. The concise form of its nutritional discussion and the assembled facts regarding foods and their handling make the work of more than passing interest or use for the limited purpose for which it was prepared.

A Text-Book of Neuro-Anatomy. By Albert Kuntz, Ph.D., M.D., Professor of Micro-Anatomy in St. Louis University School of Medicine, St. Louis. Fourth edition. Cloth. Price, $6.50. Pp. 478, with 328 illustrations. Philadelphia: Lea & Febiger, 1945.

This excellent book on neuroanatomy contains twenty-six chapters. It starts with evolution and comparative anatomy of the nervous system and concludes with the functions of the cerebral cortex. This edition is thoroughly revised and parts of it are rewritten. New data have been inserted without increasing the size of the text. Some new and improved illustrations with more complete designations have been added. This is a good book for the medical student because it is written simply and is based on the premise of structure and function. This is the ideal way of presenting a subject like neuroanatomy. The book is highly recommended.

Poor Man's Doctor. By Lewis R. Tryon, M.D. Cloth. Price, $2.75. Pp. 233. New York: Prentice-Hall, Inc., 1945.

Many a horse and buggy doctor has been telling the story of his life with much public interest. The author of this biography was born in Pennsylvania in 1872. His career brought him into the work of the Red Cross in Estonia. His travels took him pretty well around the world, yet he was always a doctor for the people. The story is told simply and directly with little artistic elaboration but with a good deal of humor and humanity.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

BREAST CANCER AND PREGNANCY

To the Editor:—Should a three months pregnancy be terminated in a patient with Paget's disease of the nipple? If so, should the breast excision be done first or the interruption of pregnancy? Captain, M. C., A. U. S.

Answer.—It seems logical to remove the breast promptly and to follow the surgery by irradiation if this course is decided on. The fate of the pregnancy would depend on several factors, such as the extent of the breast lesion, the desirability of a baby and the duration of the pregnancy. There is no unanimity of opinion concerning the role of the endocrines in breast cancer. There is some evidence that continued ovarian function favors neoplastic growth and decreases the likelihood of a cure. This has not been proved. If it is true, pregnancy, which is associated with an increase in the estrogen level of the blood, would be inimical to a favorable outcome.

If a woman who has had children is seen early in her pregnancy with a carcinoma of the breast, one could do a hysterectomy and bilateral salpingo-oophorectomy after the breast has been cared for, thereby removing ovarian function. If the same patient is seen in midpregnancy, she can be carried to viability of the child and the pregnancy then terminated by a porro cesarean section and the removal of the adnexa. In the event that the lesion of the breast is extensive when the patient is first seen, interference with the pregnancy would be of doubtful value.

PRESCRIBING SUGAR IN THE DIET

To the Editor:—It has recently been brought to my attention that some doctors are prescribing sugar. Under what conditions should one prescribe sugar, for what diseases? J. O. Chiapella, M.D., Chico, Calif.

Answer.—The conditions for which prescription of sugar is indicated are limited to those in which hypoglycemia exists. This may occur spontaneously in the presence of adenomas or other tumors of the pancreas or with pituitary, hepatic or adrenal disorders as well as with lesions of the central nervous system and emotional disturbances. An overdose of insulin in a diabetic patient would produce hypoglycemia.

The oral use of sugar in the treatment of low blood sugar should be limited to emergencies. It is no longer considered desirable to administer sugar prophylactically at intervals throughout the day, because ingestion of carbohydrate stimulates the islet cells to produce more insulin. Restriction of carbohydrate with a high fat or high protein diet has been found successful.

While quantities of lactose and other sugars may be recommended in the diets of patients with febrile conditions such as typhoid, to supply caloric value it is necessary to provide adequate amounts of the B complex vitamins to take care of the sugar. It would not be appropriate to advocate building up the caloric content of the diet with sugar to give a healthy person more energy or to increase the body weight.

UNDULANT FEVER IN LACTATING MOTHERS

To the Editor:—It has been my policy to recommend to lactating mothers with undulant fever that they should not nurse their newborn babies. Doubt has been expressed as to whether or not this is sound advice. Cecil A. Z. Sharp, M.D., Joliet, Ill.

Answer.—The available information relating to this query is small in amount and possibly inadequate as a basis for routine advice to all lactating mothers. In the light of present knowledge it seems advisable to prohibit nursing if the mothers have symptoms and signs of brucellosis throughout pregnancy or during the early postpartum period, and to permit infants to nurse if by appropriate therapy the mothers have been maintained free from symptoms not only during pregnancy but also during the early puerperium. Valuable information is found in the paper "Undulant Fever in Children," by Hagebusch and Frei (*Am. J. Clin. Path.* **11**:497 [June] 1941).

INTESTINAL PUTREFACTION

To the Editor:—Will you please advise me how to eliminate putrefaction in the bowel and stool. Give references if possible.

E. R. Hargett, M.D., Springfield, Ohio.

Answer.—Assuming that there is no obvious functional or organic derangement of the secretory and motor functions of the gastrointestinal tract and no protozoal infection or metabolic or other systemic disorder present, treatment along one of several lines may be undertaken. A tablespoon of lactodextrin (a proprietary mixture of lactose, dextrin and lemon juice) three times daily and a glass of acidophilus buttermilk twice daily has been recommended. The former is dissolved in a large glass of hot water and preferably taken an hour before each meal. In order to keep the flora changed, adequate daily evacuation of the bowels is deemed essential. This may be accomplished by the use of agar, bran, one of the plantago products or enemas in addition to the ingestion of fresh and stewed fruits, greens and such vegetables as lettuce, celery, cabbage, beets and parsnips. If tolerated, bulky or laxative foods may be used in liberal quantities, not once a day only but at every meal. According to Kellogg, the daily ingestion of proteins should not exceed minimal requirements, and meats of all sorts, including fowl and fish, should be excluded. The well cooked yolk of fresh eggs is permitted. On the basis of investigations carried out by Van der Reis purporting to show the deleterious effect of bacteria migrating from the colon to the upper reaches of the small intestine and colonization there, Rosell advocates transduodenal irrigations by living lactic acid bacterial cultures and the ingestion of generous quantities of yogurt and kefir. Other preparations that may be used singly or in addition to those already mentioned are kaolin, alumina, di-hydranol and sodium ricinoleate (soricin).

The theory that intestinal toxemia is the cause of disease is a controversial matter, and its proponents are at present on the defensive. This is strikingly shown by the fact that there has been a substantial decrease in the contributions to the subject in the past fifteen years. In the opinion of Power and Sherwin and numerous contemporaries, the human organism is provided with a chemical defense mechanism, nonspecific in character, which is more than adequate for the detoxication of the small amount of putrefactive products normally produced in the human intestine by the action of putrefactive bacteria or unabsorbed protein material. In fact, the usual bacterial flora may even be of benefit by preventing the implantation of pathogenic organisms.

URTICARIA FROM PENICILLIN

To the Editor:—A patient aged 35 years has had chronic osteomyelitis for the past twenty years. The process has involved the fourth lumbar vertebra, the left humerus and the sternum. There have been intermittent exacerbations. The most recent one involved the spine. It started as it had on numerous other occasions with malaise, low grade fever and rather severe low back pain. On the third day treatment with penicillin was started. The dosage was 30,000 units every three hours day and night. All symptoms subsided by the end of the third day. The administration of penicillin was continued, however, for a total of nine days, at which time the patient developed the most extensive case of hives that I have ever seen. Following recovery from the hives, the patient has been quite well. If this osteomyelitis shows evidence of flaring up again, is it safe to administer penicillin again? What is the likelihood of a similar reaction to this drug recurring? Should the dosage be altered in any way?

M.D., Pennsylvania.

Answer.—The reaction which is described occurs in about 2 per cent of patients who receive penicillin for a period of ten to fourteen days. If the patient needs penicillin in the future, it might be well to use an entirely different preparation; that is, a preparation of another manufacturer. In some of the cases that have been reported, a similar reaction has occurred when the drug is given a second time. In others it has not. It is suggested that, if penicillin is given in the future, the patient should be watched carefully after each dose, and, if urticaria should appear, the drug should be discontinued.

TOXICITY OF AMPHETAMINE

To the Editor.—Is there not a pharmacologic similarity between some of the actions of amphetamine and those of cocaine? Both may cause cerebral stimulation or excitement, diaphoresis, tachycardia, rise of systolic pressure and wakefulness This strong resemblance has never received much comment in the literature. Has such comparison ever been made? Cocaine used steadily in time usually results in complete or nearly complete impotence. Has such an end result ever been ascribed to amphetamine? Several years ago The Journal described the death of a student after taking about 15 mg. of amphetamine Have any other fatalities been reported?

M.D , Illinois

Answer—The signs and symptoms caused by cocaine are similar to those due to stimulation of the sympathetic nervous system; the analogy is not perfect, however. Sollmann in his "Manual of Pharmacology" points out that the symptoms of cocaine poisoning resemble those of ephedrine. Ephedrine is closely related to amphetamine, except that the latter has much less vasopressor effect Waud (The Journal, Jan. 15, 1938, p. 206) reported that, in the absence of collapse, the toxic effects of large doses of amphetamine resemble excessive stimulation of the sympathetic nervous system.

Ephedrine is known to prevent erection in some patients. The parasympathetic vasodilator fibers in the pelvic nerves (nervi erigentes) are the nerves of erection. Ephedrine stimulates vasoconstrictor nerve endings and probably in this way prevents erection in some subjects. Libido in man is reported to be increased in some subjects. Since it has been observed that amphetamine, like ephedrine, tends to inhibit erection, the augmentation of libido is probably due to the elevation of mood caused by the amphetamine (Ivy, A. C., and Krasno, L. R.: Amphetamine (Benzedrine) Sulfate: Review of Its Pharmacology, *War Med.* **1**:15 [Jan.] 1941).

Collapse after large doses (30 to 450 mg.) has been frequently reported. Some patients have tolerated as much as 160 to 200 mg. a day; on the contrary, several apparently normal subjects have collapsed after taking 30 mg. at one dose. The student referred to in the question had apparently taken only 30 mg. within five days and 10 mg. a few hours prior to collapse and death, the cause of death being conjectural. Since then apparently only one other death ascribed to amphetamine has been reported. Hertzog, Karlstrom and Bechtel (The Journal, Jan. 23, 1943, p. 256) reported the death of a child 12 months old who had swallowed 40 mg or more of amphetamine plus an unknown amount of ferrous sulfate tablets.

VACCINATION FOR INFLUENZA

To the Editor.—In the Army in Arkansas wholesale vaccinations are being given for influenza. The virus is cultured in the allantoic sac of the egg. Where can I get some information on this vaccine? Can it be used on children and if so what is the dosage?

William J. Schirmer, Captain, M C, A U. S

Answer.—The description of the character of the vaccine being employed against influenza and information concerning its use are published in detail in the *American Journal of Hygiene* **42**:1-105 (July) 1945. This constitutes a series of seven papers which provide data as to its use. The material can be used for children, but the amount should probably be reduced, although accurate determination of the reactions in children with such preparations has not been made. Additional care should be taken to avoid individuals sensitive to eggs

GLUCOSE ADMINISTRATION IN CEREBRAL HEMORRHAGE

To the Editor.—Is the administration of glucose indicated in apoplexy, even when the patient is unconscious? Should not fluids be restricted to avoid more damage to the brain?

J. O. Helm, M D., New Florence, Mo

Answer.—The value of any active treatment during the coma stage of cerebral hemorrhage is arguable. The occurrence of such a major crisis, however, prompts a great desire to do something. One of the reactions to cerebral hemorrhage is the occurrence of cerebral edema. It is assumed that the introduction of a hypertonic glucose solution into the circulation reduces the cerebral edema by the transport of fluid from the tissues to the blood stream. The introduction of such glucose is followed by a considerable diuresis. To bring this about, 50 cc. of a 50 per cent solution of glucose is introduced intravenously. It is doubtful that this amount of fluid, less than 2 ounces, will upset the dynamics of the circulation.

The introduction of large amounts of glucose solution into the circulation is not good treatment. If it is necessary to replace fluids, another avenue should be used and, to introduce food, tube feeding or even rectal feeding should be employed rather than intravenous injection.

LUPUS ERYTHEMATOSUS—BISMUTH IN HYPERTENSION

To the Editor.—A facial lesion of a year's duration in a woman aged 45 was diagnosed lupus erythematosus after biopsy; gold therapy was outlined by a competent dermatologist For the past six years the systolic pressure has been 180 to 200 and the diastolic 105 to 120. She has a history of illness suggestive of acute rheumatic fever, but there has been no evidence of involvement of the heart while she has been under my care However, the sedimentation rate is consistently 20-24 mm in one hour. Having heard of the use of bismuth subsalicylate in oil in the treatment of lupus erythematosus, I would appreciate a comparison of its effectiveness and safety in a patient with hypertension and possible rheumatic heart history.

Hubert C. Miller, M D, Racine, Wis

Answer—Bismuth subsalicylate in oil has been tried by a number of clinicians for the treatment of lupus erythematosus but without encouraging results. The cause of this disease is unknown, and there is no theoretical reason why this preparation should be effective in arresting or ameliorating the clinical manifestations of the disease. Although there are no contraindications to the use of bismuth subsalicylate because of the possible existence of rheumatic heart disease, there may be some hazard in using it on a patient with arterial hypertension. An accelerated arteriosclerosis (so-called malignant hypertension) has been observed to follow the administration of bismuth to patients with essential hypertension. Bismuth may also damage the renal convoluted tubules, especially when administered to patients with a febrile illness such as lupus, which is often associated with considerable toxic damage to the renal parenchyma and specific necrosis of renal arterioles and capillaries.

HEALING OF WOUNDS AND LOW VITAMIN C INTAKE IN ICELAND

To the Editor.—I am interested in the problem of nutrition where there is a shortage of vitamin C In The Journal June 30, 1945 there is an article on this subject from your correspondent in Iceland, and I was wondering whether they have made any investigations on the healing of wounds, having in mind especially the low vitamin C intake I am now making an extensive study of the causes of delayed healing, referring especially to late post-tonsillectomy hemorrhage Are there any reports on the incidence of this condition among the Icelanders?

Harry Neivert, M D, New York

Answer.—In spite of the low intake of vitamin C in Iceland, delayed healing of wounds has not been observed—at least not in any degree diverging from what is considered normal in other countries.

The only people in whom this condition has been seen in a striking degree are the leprous. A sutured wound in a patient with leprosy is frequently hardly glued together after seven days. In these patients the vitamin C content has been found lower than in the general population, the urinary excretion being as a rule below 10 mg. per day and not infrequently as low as 6 mg.

Hemorrhages after tonsillectomies are rare, occurring in only 1 to 2 per cent of the cases. Experienced doctors who have been trained abroad are convinced that these hemorrhages are no more frequent than elsewhere, if not less so.

STORAGE OF PENICILLIN

To the Editor—Please inform me how rapidly penicillin in powder will lose its potency if kept in an atmospheric temperature of around 25 C. Efficient refrigeration is often difficult to obtain nowadays in the Philippines, especially in the field.

Jose F. Tangco, Captain, M C, Manila, P. I.

Answer—Penicillin in powder form may be kept at a temperature of around 25 C. and retain its potency for at least six months, perhaps longer, if the drug is kept in protected package form.

HYPERTENSION AND CERVICAL RIB

To the Editor—In the answer to a query published in The Journal Nov. 24, 1945, page 916, cervical rib was mentioned as a probable cause of tingling sensations in the shoulder. It was reported that the patient presented an arterial tension of 185/110, but no mention is made as to whether the blood pressure was symmetrical in the two arms. Asymmetry of the arterial tension is so common in cases of cervical rib that the latter lesion always should be suspected when asymmetry is discovered, even if otherwise the patient is asymptomatic. The pressure is usually much lower on the side on which symptoms of cervical rib occur. Hypertension on the opposite side may be compensatory; this has been demonstrated in at least 1 case (Propst, D. W., and Stieglitz, E. J.: Differential Arterial Tension, *Am. J. M. Sc.* 184:336 [Sept.] 1932), in which freeing of the cervical rib reduced the hypertension on the opposite side It is an excellent rule to determine the blood pressure on both arms at least once with every patient. If found symmetrical (within 5 mm. of mercury) this procedure need not be repeated. Asymmetry is not discovered unless searched for.

Edward J Stieglitz, M D, Washington, D. C.

TREATMENT OF MIXED INFECTIONS WITH PENICILLIN

I. With Special Reference to the Adjuvant Action of Parachlorophenol

In the course of our study of established infections during the past year and a half, it has been demonstrated frequently that penicillin is of questionable benefit or no benefit at all in the treatment of many infections in which there is a mixture of organisms. In some of these infections there is undoubtedly a synergistic action on the part of the bacteria in the production of the pathologic process. In other cases, secondary contaminants which are not pathogenic or are only feebly so, under ordinary circumstances, are able to multiply in the presence of wound exudate or dead tissue.

Using the wound as a culture medium, these organisms produce metabolic products which may be toxic locally to the tissues of the wound or may be absorbed by the body and give rise to general symptoms. Certain of these metabolic products may also destroy the growth-inhibiting action of penicillin. Abraham and Chain[1] believe this destructive agent to be an enzyme and named it "penicillinase." Its enzymatic nature is further substantiated by the work of Woodruff and Foster.[2] Among the different bacteria which produce this enzyme is the large group of aerobic non-spore forming gram-negative rods, particularly the coliform, the proteus and the pyocyaneus bacilli.

Some strains destroy relatively large amounts of penicillin rapidly, others inactivate it much more slowly or not at all. When the inactivation is slow, this may be offset by increasing the number of units of penicillin in a given dose. The level of penicillin in the wound may thus be kept sufficiently high to eliminate susceptible species, such as hemolytic streptococci or Staphylococcus aureus. If such a level cannot be maintained, the penicillin will not have the expected beneficial effects. A consistent reduction of the level below that required for the bacteriostasis of "susceptible" strains carries with it an additional hazard, since, under these circumstances, the previously "susceptible" strain may acquire resistance and become penicillin fast. It has become increasingly important, therefore to find an antibacterial agent which will eliminate these gram-negative organisms when they are present in mixed infections or in contaminated accidental wounds of soft parts, compound fractures and burns.

As soon as it became apparent in the early part of the study that mixed infections did not respond favorably to penicillin, we planned a series of laboratory experiments. All gram-negative organisms isolated from wound infections were tested for their destructive action on penicillin "in vitro" and for their susceptibility to a series of antibacterial agents known to be effective against gram-negative organisms. We also tested the compatibility of penicillin and these agents in isotonic solution of sodium chloride and in a carbowax 4,000-propylene glycol base. It was our plan to select the agent most effective against the gram-negative bacteria in each individual case and to use this agent in combination with penicillin in the treatment of the infection.

DESTRUCTION OF PENICILLIN IN VITRO BY GRAM-NEGATIVE ORGANISMS

We have tested 134 strains of gram-negative bacteria isolated from wound infections for their destructive action on penicillin. In the majority of these tests we assayed the extracellular penicillinase only. To 1 cc. of an overnight broth culture of the test strain was added 1 cc. of a penicillin solution containing 40 units per cubic centimeter. A control was set up using 1 cc. of beef infusion broth plus 1 cc. of the penicillin solution. These mixtures were incubated for two hours at 37 C. and then tested for penicillin content by the agar plate-penicylinder method against the Oxford strain of staphylococcus.

We repeated the tests with fresh cultures of all strains showing complete or no destruction of the penicillin in the two hour period and the results were essentially the same. In repeat tests with strains which showed partial inactivation there was at times as much as 25 per cent variation in the results, but in no case did we get no inactivation in the retests of these slow inactivators. In certain experiments we used penicillin in human plasma and whole blood to add to the broth cultures of the organisms. Neither the plasma nor the whole blood protected the penicillin from the action of the bacterial penicillinase. Of particular interest to us was the rapid inactivation of the penicillin by the groups of Achromobacters and gram-negative micrococci, organisms which would usually be considered relatively unimportant members of the bacterial flora of the infection. In one infection there was clinical evidence that the gram-negative coccus was inactivating the penicillin in vivo

---

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the Columbia University College of Physicians and Surgeons

since, until it was eliminated from the wound by p-chlorophenol, the infection did not respond to penicillin therapy.

We do not wish to create the impression that the gram-negative organisms are the only bacteria in wounds which may destroy penicillin. The great majority of the aerobic gram-positive spore-forming bacilli (B. subtilis group) isolated from mixed infections completely destroyed the growth inhibiting action of 250 to 500 units of penicillin per cubic centimeter rapidly, and the naturally resistant strains of staphylococci also inactivated penicillin.

ANTIBACTERIAL AGENTS EFFECTIVE AGAINST GRAM-NEGATIVE ORGANISMS

During the past two years we have tested over two hundred chemical compounds and antibiotic agents for their antiseptic action on aerobic gram-negative bacteria. Unfortunately the great majority of the agents which have a bacteriostatic action in vitro are not suitable for clinical use. An antiseptic should be active in the presence of organic matter and should be able to penetrate into pus or wound exudates and into surrounding infected tissues. It should be soluble or miscible in water in concentrations which will permit further dilution by body fluids and still retain bacteriostatic activity. It must inhibit the multiplication of the bacteria in dilutions which can be tolerated by the tissues, and it should not unduly retard wound healing. Many agents which are highly toxic if administered systemically may be used for local application to infected wounds, since the amount absorbed into and present in the body at any one time is not sufficient to produce a general toxicity.

Among the agents which seem to meet these conditions and therefore are worthy of extensive laboratory and clinical studies are p-chlorophenol, 9-amino-acridine hydrochloride, 5 nitro-2 furaldehyde semicarbazone, streptothricin and streptomycin.

THE HALOGENATED PHENOLS

Of the halogenated phenols which we have tested in vitro, p-chlorophenol seemed to give the most promise of success for clinical use. Klarmann and his associates[3] reported in 1934 that the bacteriostatic and bactericidal action of the halogenated phenols increased with the atomic weight of the halogen atom. The compounds with the halogen atom in the para position were found to be more active than those with the halogen atom in the ortho position on the phenol ring. We reevaluated p-chlorophenol, p-bromophenol and p-iodophenol but found that, under our experimental conditions, the differences in bacteriostatic activity against gram-negative organisms was too small to offset the increase in the toxicity which accompanied the increase in weight of the halogen atom. Klarmann and his associates[4] had also reported that the introduction of the aliphatic and aromatic groups into the halogenated phenols increased the bacteriostatic action and decreased the toxicity. N-amyl-p-chlorophenol was the most bacteriostatic and the least toxic. However, the low solubility of this compound in water more than offset the increase in germicidal activity when compared to p-chlorophenol in our tests. We also tested 4-chloro-o-phenyl phenol and 0-(2, 3, dichloropropyl) phenol but the margin between the concentration necessary for bacteriostasis and the maximum solubility of these compounds in water was too small to permit dilution by body fluids or wound exudates. We therefore focused our attention on p-chlorophenol.

PARACHLOROPHENOL

Physical Properties and Toxicity.—This compound[5] is readily soluble in water or in isotonic solution of sodium chloride in a concentration of 1:200. For clinical use a 1:400 concentration in isotonic solution of sodium chloride or in a carbowax 4,000-propylene glycol (45 to 55 per cent by weight) ointment base was used for local application to infected wounds Its systemic toxicity when injected subcutaneously into mice is 0.6 mg. per gram of body weight. A corresponding dose for man would be 40 Gm., or about 16 Kg. of ointment as prepared for clinical use, which is well above any amount likely to be used. In solution and in the carbowax ointment it has a not unpleasant phenolic odor.

Bacteriostatic and Bactericidal Properties.—For our "in vitro" studies we made up the desired concentrations of p-chlorophenol in beef infusion broth, p_H 7.2, tubed in 5 cc. amounts. We used a heavy inoculum, 0.05 cc. of an overnight culture, to seed the experimental and control tubes. The results of our tests on 140 freshly isolated strains of Gram-negative bacteria are given in table 2.

TABLE 2—*Bacteriostatic Action of P-Chlorophenol on Gram-Negative Bacteria*

		[illegible]		
Organism	Strains	1 1,000	1 2,000	1 5,000
E coli .	44	5	28	11
Coli intermediates	10	0	9	1
Aerobacter ..	6	0	5	1
B pyocyaneus	36	5	19	12
Proteus. .	28	1	27	2
Achromobacter	5	1	0	4
B alkaligenes	3	0	0	3
S alcalescens	2	0	1	1
E typhosus	2	0	1	1
K friedlanderi	1	0	0	1
Micrococcus	3	0	0	3

The concentrations given are those which completely inhibited the multiplication of the organisms after seventy-two hours' incubation at 37 C. The bactericidal level was very close to the bacteriostatic level. In no instance when the tubes were plated after twenty-four hours' incubation at 37 C. were there viable organisms in the 1:1,000 dilution of the p-chlorophenol in beef infusion broth.

Compatibility with Penicillin.—We have tested the compatibility of calcium and sodium penicillin with p-chlorophenol in isotonic solution of sodium chloride and in the water soluble carbowax 4,000-propylene glycol ointment. Mixtures of sodium or calcium penicillin 250 to 500 units per gram and p-chlorophenol 0.25 per cent showed no loss of penicillin titer when tested after two weeks' storage at 5 C. After six to twelve weeks' storage, there was a decrease in penicillin activity amounting to approximately 50 per cent. We also determined whether p-chlorophenol had a rapid destructive action on penicillin at body temperature. After forty-eight hours at 37 C., the titer of the penicillin combined with 0.25 per cent p-chlorophenol had not dropped. It would seem therefore that for all practical purposes penicillin and p-chlorophenol may be combined for application to infected wounds.

The ointment is prepared by melting 45 parts of carbowax 4,000 with 55 parts of propylene glycol together either over a free flame or in a hot water bath. When they are thoroughly mixed they are sterilized in a dry oven at 140 C. for four hours and then allowed to cool. As they begin to solidify at 40 C. the penicillin (1,000 units per gram) and parachlorophenol (0.25 per cent) are added. At this stage the ointment may be incorporated sterilely into fine meshed gauze (piece by piece cut to a convenient size) and placed in a pile of fifty or more in a container. A pint or quart sized ice cream box serves as an excellent container. Both the ointment and the impregnated gauze should be kept in the ice box until ready for use.

Clinical Results.—We have never seen any evidence of local or general toxic reaction from the local application of 0.25 per cent p-chlorophenol, although some patients have complained of a slight burning sensation for a short time after it was applied. Dr. Howes tested for us its effect on the healing of experimentally produced wounds of the rabbit's ear and there was no appreciable inhibition. Sinus tracts may be irrigated with a 0.25 per cent solution in isotonic solution of sodium chloride, but for local application to wound surfaces we prefer 0.25 per cent p-chlorophenol in carbowax 4,000-propylene glycol ointment. This may be applied directly or may be impregnated in fine mesh gauze.

The use of p-chlorophenol in wounds infected with gram-negative organisms has given very gratifying results. It eliminated Proteus vulgaris from an osteomyelitis wound when that organism was rapidly destroying recent skin grafts. It did this promptly after its application, although previous treatment with streptothricin had failed. A gram-negative micrococcus was eliminated from another compound fracture wound when the development of granulations had come to a standstill. After its application, granulations promptly started to grow and permitted skin grafting within a few days. It caused the disappearance of a typhoid bacillus after two days' application in a case of typhoid osteomyelitis. It eliminated B. pyocyaneus from a very extensive osteomyelitic cavity in the femur and also from a cecostomy wound in which the pyocyaneus was growing luxuriantly.

P-chlorophenol (0.25 per cent) was used in combination with penicillin (250 units per gram) in the carbowax-propylene glycol base in a very extensive ulcerating infection of the vagina, vulva, perineum and groins following a partial colectomy in a case of chronic ulcerative colitis. This infection cultured a group C hemolytic streptococcus, a coagulase positive hemolytic Staphylococcus aureus, a nonhemolytic streptococcus, Clostridium welchi and an anaerobic gas-forming gram-positive micrococcus, all sensitive to penicillin, Proteus vulgaris, resistant to penicillin and Escherichia coli and resistant to and destructive of penicillin. The p-chlorophenol stopped the destructive action of the E. coli on the penicillin and the ulcers healed rapidly. P-chlorophenol combined with penicillin also eliminated all the organisms from a chronic ulcer of the leg from which proteus, nonhemolytic streptococci and an anaerobic gas-forming gram-positive micrococcus had been cultured and the wound, which had become completely stagnant, was soon epithelized.

Recently we have had some difficulty ridding an operative wound of Pseudomonas pyocyanea in a case of chronic osteomyelitis of the tibia with epithelioma in the old osteomyelitic scar. The cultures yielded hemolytic Staphylococcus aureus and Ps. pyocyanea. The Ps. pyocyanea produced penicillinase. The tumor and scar and the diseased bone were removed and the wound dressed with a silk tampon packed with gauze soaked in an aqueous solution of penicillin 1,000 units per cubic centimeter and 0.25 per cent parachlorophenol. The Ps. pyocyanea was held in check and the wound granulated and accepted skin grafts throughout the area except at one small spot 6 by 3 mm. in diameter on the marble-like eburnated bone, where the bone remained bare and the cultures of Ps. pyocyanea have persisted. This may require further excision of the diseased bone.

In another recent case of chronic osteomyelitis of the femur with sinuses in the thigh, sequestrums around the lesser trochanter and a urinary fistula through the thigh sinuses from which cultures yielded hemolytic Staphylococcus aureus, Ps. pyocyanea (producing penicillinase), Proteus vulgaris and a nonhemolytic streptococcus, the sinus tracts were excised and the sequestrums were removed but the fistula was not closed. The wound was dressed with a silk tampon and puddled with an aqueous solution containing penicillin 1,000 units per cubic centimeter and parachlorophenol 0.25 per cent. Ps. pyocyanea persisted for several weeks but finally disappeared when streptothricin 250 units per cubic centimeter was added to the mixture. The Proteus vulgaris and urinary fistula still persist.

These are the only cases in which Ps. pyocyanea has failed to respond promptly to the local application of parachlorophenol, and we believe the physical nature of these wounds prevented adequate contact. Both may require further operative procedures.

SUMMARY AND CONCLUSIONS

1. The treatment of surgical infections with penicillin makes it of the utmost importance to have a complete picture of the bacterial flora of such infections and to know whether the organisms are susceptible, indifferent or antagonistic to penicillin. The destructive action of the aerobic gram-negative non-spore forming bacteria should be anticipated and attempts to eliminate them should be made before "susceptible" species have developed resistance to penicillin.

2. Of the antiseptics so far tested and which are available at present, p-chlorophenol is the most effective antibacterial agent against gram-negative organisms. In a concentration consistent with clinical safe application, it was bacteriostatic and bactericidal for all the

gram-negative organisms tested, whereas 9-aminoacridine hydrochloride and 5 nitro, 2 furaldehyde semicarbazone were not effective against Ps. pyocyanea.

3. The individual strain susceptibility of the gram-negative organisms isolated from any given infection should be tested for the inhibitory action of parachlorophenol, 9-aminoacridine, 5 nitro, 2 furaldehyde semicarbazone, streptothricin and streptomycin, since the sensitivity of different strains within the same species as well as the sensitivity of different species varies greatly.

4. All of these agents are compatible with penicillin and may be combined for local application to infected wounds.

5. They may be incorporated in a carbowax-propylene glycol base for local application and prolonged action in wounds.

The effect of agents other than parachlorophenol will be reported in subsequent papers.

CHEMOPROPHYLAXIS AND SULFONAMIDE RESISTANT STREPTOCOCCI

LIEUTENANT COMMANDER DOUGLAS S DAMROSCH (MC), U S N R

The use of sulfonamide drugs for the prevention of streptococcic infections and rheumatic fever has been employed by several groups of workers,[1] with generally favorable results In 1943 Watson and his associates[2] used sulfadiazine to interrupt the course of a scarlet fever epidemic in a small naval activity in New York.

In 1943, faced with disturbingly high morbidity rates from streptococcic infections in several naval recruit training centers, a program of chemoprophylaxis was instituted on a scale much larger than that previously employed. The experience during the first six months of that program was highly gratifying.[3] In general there was a reduction in the incidence of streptococcic infections to approximately 15 per cent of the expected rate, as shown in control groups which did not receive the drug.

However, during the following season, the fall and winter of 1944-1945, chemoprophylaxis failed in a number of instances. The development of a satisfactory in vitro test for sulfonamide resistance of group A beta hemolytic streptococci[4] made it possible to attribute this failure to the prevalence of strains which were highly resistant to the drug which was being used prophylactically.

My purpose in this paper is to present the events which occurred following the appearance of sulfonamide resistant group A streptococci in three small training schools in which chemoprophylaxis was used.

DESCRIPTION OF THE SCHOOLS

The three school buildings, which may be called School Red, School White and School Blue, before occupation by the Navy, had been parts of the school system of a large Midwestern city. Red and Blue were junior colleges, and White was a high school. Architecturally they were quite similar, all being three-storied brick or stone buildings. They contained classrooms for 40 or 48 students each, an auditorium, a gymnasium, offices and a cafeteria. School Blue had a single gymnasium but no swimming pool. Schools Red and White each had two gymnasiums and a swimming pool. As all three were day schools, there was no provision for berthing.

The school buildings were taken over by the Navy in 1943 and 1944 for use as training schools in one of the naval specialties School Red was occupied by the Navy in the fall of 1943, White early in 1944 and Blue in the summer of 1944. Conversion to meet naval needs involved minimal structural changes. The gymnasiums and some of the classrooms were used as berthing facilities The remaining classrooms retained their original function. Additional toilet facilities were installed. In each a medical department, staffed by a medical officer and hospital corpsmen, was installed and consisted of a dispensary and one or two wards. The latter were used for the care of minor illnesses and injuries, the more serious or prolonged cases being transferred to a nearby naval hospital.

The pressing demands of the naval training program made necessary a certain amount of compromise with accepted hygienic standards in many instances This was true at the schools being discussed, and in each the exigencies of the service and space available for berthing led to crowded sleeping arrangements Triple decked bunks were employed throughout. At School Red 400 men were housed in each of the two gymnasiums, containing in each instance 6,000 square feet of floor area and 168,000 cubic feet of volume. The smaller bunk rooms housed from 51 to 69 men and contained 720 to 960 square feet of floor area and 10,080 to 13,440 cubic feet of volume respectively. At School White the two gymnasiums berthed 420 men each and the measurements of both were 5,975 square feet and 155,350 cubic feet The smaller bunk rooms berthed 30 to 75 men, and their measurements ranged from 735 to 1,795 square feet and 9,552 to 23,335 cubic feet respectively. At School Blue 240 men slept in the gymnasium (4,500 square feet and 90,000 cubic feet) and from 36 to 60 in the smaller bunk rooms (750 to 1,500 square feet and 11,250 to 22,500 cubic feet).

Spacing of bunks varied somewhat, but in few instances was the space between bunks in excess of

4 feet. In many rooms the bunks were arranged in blocks of six (i. e. two triple decked bunk sections) with no space between the sections. The men were required to sleep head to foot throughout.

Most of the training at these schools was done in classrooms which required no alteration. Previously existing laboratories were used for special technical work, and some classrooms were converted to that function. The nature of classroom and laboratory work was not in itself of any special consequence as a health hazard.

PERSONNEL

The training course at the three schools was of three and one-half weeks' duration. Trainees were received direct from the several recruit training centers in various parts of the country. The trainees were therefore men who had been in the naval service for a relatively short time. Their past history is, briefly, as follows: After induction these men were sent to a recruit training center, where for approximately ten weeks they were given an intensive course including physical drill and basic naval studies. In addition they received a series of immunizations (smallpox, typhoid and paratyphoid vaccine, yellow fever vaccine and tetanus toxoid). At the conclusion of the training course the men were given ten to fifteen days' leave during which most returned to their homes. At the expiration of leave they returned to the outgoing unit of their recruit training center to await further assignment. It was from such units that trainees at Schools Red, White and Blue were received. On arrival, usually in large groups, the trainees were assigned to companies of about 50 men in each.

During the training period of three and one-half weeks the men received intensive didactic training which necessitated much study and relatively little time off. Liberty was granted one evening each week and from Saturday noon until Sunday night, at which time the trainees were free to engage in whatever recreational activities in the city they desired. At the end of the training period, graduates were transferred to other schools and new groups were received. During these transition periods, occupying one week, there was some mixture of outgoing and incoming groups. Usually the majority of outgoing men had departed before any substantial number of new trainees arrived. There was very little traffic between Schools Red, White and Blue. In each period there was a relatively small group which was held over for the next course, being those men who were allowed to repeat the course having been ill or otherwise deficient during their regular course.

In addition to trainees, each school had a relatively stable group of permanent personnel who served as instructors and carried out administrative duties. This group represented approximately 10 per cent of the personnel at each school. The observations in this paper are confined to the trainees.

PAST EPIDEMIOLOGIC EXPERIENCE

Only one of the schools (Red) had been in operation during the entire winter of 1943-1944. The experience of School Red during that period served to point out some of the epidemiologic characteristics of all three, however, and offered indications as to the necessity of institution of streptococcic disease control. Table 1 summarizes the experiences of School Red with respect to certain acute respiratory infections during the winter of 1943-1944.

It must be borne in mind that the population of the schools was not a static one. Each month a new group of trainees arrived, and this represented a continuous inflow of susceptible individuals. Trainees were found to present varying degrees of infection on arrival, reflecting to a great extent the incidence of infection at the recruit training centers whence they came. In general, during the summer months, trainees arrived relatively free of infections, as indicated by low rates of illness during the week following arrival, and remaining free of infection during their training course. In fall and early winter, comparatively few were ill during the first week of their stay but the incidence of disease rose sharply thereafter, reaching a peak shortly before the end of the training period. In midwinter many more men were ill on arrival or became ill during the the first few days on the station, and thereafter, as before, the incidence rose gradually during the remainder of the training period.

	Second Period					
Dec. 12 to Dec. 22	14	392	25.0	11	436	17.6

When School White went into commission in February 1944, it promptly began to show an incidence and behavior of respiratory disease comparable to that at Red. School Blue had not opened until the summer of 1944 and therefore furnished nothing on which to predict the winter's morbidity other than a close resemblance to White and Red from the standpoint of hygienic circumstances. On the bases of the latter, high respiratory morbidity was anticipated.

During the summer of 1944 all three schools were relatively free of infection, with only 1 or 2 admissions a week for respiratory disease. During October they simultaneously began to show a progressive rise, and by the first of November each had attained a total respiratory rate in excess of 500 per thousand annually. It was therefore decided to institute chemoprophylaxis.

METHOD OF STUDY

For a period of approximately one month prior to the institution of chemoprophylaxis, throat cultures were done on all men admitted to the sick list with acute respiratory infections. This was done in order to determine the streptococcus flora during that period.

The general plan for the administration and study of sulfadiazine prophylaxis was essentially the same at the three schools. The trainees were divided into two approximately equal groups, one group to receive prophylaxis and the other to serve as untreated controls. The assignment to the groups was made by taking alternate companies of about 50 men each. Companies were made up as the men reported for training. Throughout the study, control and treated groups in a particular school were in close association with one another, since in most instances they were bunked together and shared the messing, training and recreation facilities.

The treated group received a daily dose of 1 Gm. of sulfadiazine throughout the three and one half weeks of the training course. The control group received no medication. When any man in either group was admitted to the sick list with an acute respiratory infection, a throat culture was done. In addition, from members of the treated group who developed such infections blood was drawn for determination of sulfadiazine level. Both procedures were done at the time the men were admitted to the sick list, usually at morning sick call, from eighteen to twenty-four hours after their last dose of sulfadiazine. Throat swabs were placed in tubes containing broth, collected once daily by the Epidemiology Unit and transported to the laboratory, where they were inoculated into sheep's blood-agar pour plates. From plates positive for beta hemolytic streptococci a colony was fished, grown out in tryptose phosphate broth and grouped. Group A strains were sent to the streptococcus typing laboratory at the Naval Medical School in Bethesda, Md., where typing and resistance studies were done. Typing was done by the capillary precipitin method of Swift, Wilson and Lancefield.[5]

At the end of the training period of three and one-half weeks, prophylaxis was discontinued in each case for one week during which time drafts were arriving and departing. The process of assignment to treated and control groups was then repeated and prophylaxis resumed.

Men who became ill were hospitalized and therefore removed from their groups, usually not returning to duty until the next training period. Fitness for return to duty depended on the man's clinical condition, no attempt at bacteriologic control of convalescent carriers being made. Men with mild respiratory infections remained on duty and are not considered as admissions nor were they confined.

RESULTS

School Blue.—During the preliminary period of study (October 18 to November 14) before chemoprophylaxis was begun, throat cultures were done on 111 men admitted to the sick list with acute respiratory infections. From 45 of these, group A streptococci were recovered. Of these, 20 were type 19, 18 were type 17 and 3 were type 3, and in 4 the type was not determined. Of forty of these strains tested, none showed in vitro resistance to sulfadiazine.

The first period of chemoprophylaxis extended from Nov. 15 to Dec. 5, 1944. During this time there were 26 Group A streptococcic infections in the control group and 5 in the treated group. Of the latter, 1 individual showed no blood sulfadiazine, 3 showed traces and 1 showed a level of 1.7 mg. per hundred cubic centimeters. During this period four of the strains were found to be resistant, 2 occurring in the control group and 2 occurring in the treated group. The first of the resistant strains was recovered five days after the use of sulfadiazine was begun. Three of the resistant strains were of type 19 and one was type 17. Susceptible strains included these two types and in addition types 3 and 36.

During the period from December 5 through December 11, prophylaxis was started in half of the new trainees. During the next ten days there were 14 group A infections in the control group and 10 in the treated group in spite of the fact that most of the men in the treated group had blood sulfadiazine levels of at least 1.5 mg. per hundred cubic centimeters. When the reports of resistance studies became available, it was found that 10 strains of 18 tested during this period showed resistance in vitro. All of the resistant strains were of type 19, while the susceptible strains included types 19, 17 and 3. Five of the resistant strains occurred in the treated group and five in the control group.

[5] Swift, H. F.; Wilson, A. T., and Lancefield, R. C.: Typing Group A Hemolytic Streptococci by M Precipitin Reactions in Capillary Pipets, J. Exper. Med. 78: 127-133 (Aug.) 1943.

Wilson's test for sulfonamide resistance is performed by measuring the ability of small inoculums to grow in the presence of varying concentrations of sodium sulfadiazine in a semisolid, semisynthetic medium reinforced with horse serum. Strains inhibited by 5 mg. or more of sodium sulfadiazine per hundred cubic centimeters of medium were considered susceptible. Those which grew in the presence of 5 mg. or more per hundred cubic centimeters of medium were considered resistant.

On December 22 the controlled study was abandoned in an effort to curb the rising morbidity, all trainees being at that time included in chemoprophylaxis. By Jan. 2, 1945, however, it had become obvious that the drug was having little or no effect. The incidence of group A infections remained high even though practically all of the men becoming infected had high blood levels. At that time the epidemiologic impression that chemoprophylaxis was no longer effective was substantiated by reports received from the Bethesda laboratory that strains of streptococcus showed in vitro resistance to sulfadiazine. Chemoprophylaxis was therefore discontinued. During the eleven days when all trainees received sulfadiazine there were 58 group A infections admitted to the sick list, including 24 cases of scarlet fever. Forty strains from these men were typed and all but one found to be type 19 (the other could not be typed). Of twenty-two of these strains tested for resistance, 16 were resistant and 6 susceptible to sulfadiazine in vitro.

School Red.—During the preliminary period of study (October 20 to November 13) before prophylaxis was begun, throat cultures were done on 67 men admitted to the sick list for acute respiratory infections. Group A hemolytic streptococci were recovered from 21. Ten were type 17, one type 19, two type 3, and the remaining eight were not typed. Sixteen cultures were tested for resistance but none was resistant.

The first period of controlled chemoprophylaxis was, as at School Blue, successful. In the control group there were 39 group A streptococcic infections and in the treated group there were only 5. During this period three resistant strains were recovered, two in the control group and one in the treated group. The first one (a type 17 strain) was recovered only three days after chemoprophylaxis began from a case of scarlet fever occurring in the treated group. The other two resistant strains belonged to types 17 and 3 respectively.

When the new group of trainees who arrived during the period December 4 to December 10 was started on chemoprophylaxis, the infection rate in the treated group was considerably lower than in the control group during the first week. For the next two weeks, however, infections increased in the treated group, even though satisfactory blood sulfadiazine levels were being found in most men. Five showed no blood sulfadiazine, 15 showed levels of less than 1 mg. per hundred cubic centimeters and 20 had levels over 1 mg. per hundred cubic centimeters. During the first week of this period, four more resistant strains appeared, two (both type 3) in the control group and two (types 3 and 17) in the treated group. During the whole period (December 11 to January 2) eleven of thirty-five (32 per cent) of the strains tested from the control group were resistant. Susceptible strains seemed to have disappeared from the treated group, since of eleven strains tested all were resistant. The resistant strains belonged to types 17 and 3.

School White.—During the period October 18 to November 6, before chemoprophylaxis was started, throat cultures were done on 54 respiratory admissions and group A hemolytic streptococci were recovered from 11. Four of these belonged to type 19, two to type 3 and one each to type 17 and 28. Of eight strains tested, none was resistant to sulfadiazine.

The first period of controlled chemoprophylaxis began on November 6 and extended for two weeks, having been started after the men had been in training one week. In the control group there were 10 group A infections, while the treated group had none. From the 10 infected men in the control group, organisms of types 3, 17 and 19 were recovered, all susceptible to sulfadiazine in vitro.

The second period (December 11 to January 2) began favorably and for the first two weeks infections were considerably higher in the control group than in the treated group. During the final nine days, however, there were 13 infections in the treated group as compared with 19 in the controls. The first resistant strain appeared on the third day of the prophylaxis and occurred in a member of the control group. This man had arrived one week previously from a recruit training center where resistant strains are known to have been present. During the next ten days only two more resistant strains appeared, one each from the controls and treated groups. During the final weeks, however, an abrupt increase in the prevalence of resistant strains took place coincident with the increase in infections in the treated group. During this whole period of forty-one strains from the control group tested, ten (24 per cent) were found to be resistant in vitro. In the treated group twelve of fifteen strains (80 per cent) were resistant. Types 17, 19, 3, 30 and 6 were all encountered during the period, but resistant strains all belonged to type 3.

SUMMARY AND COMMENT

In November and December of 1944 a controlled program of chemoprophylaxis against hemolytic streptococcus infections was employed in three small naval training schools. The incidence of such infections had, both during the period of observation and in the past, reached epidemic proportions. The factors considered to have predisposed to this condition are as follows: (*a*) Owing to the exigencies of the service, crowded living conditions unavoidably prevailed; (*b*) there was a repeated introduction of susceptible individuals because of the fact that each month there was a nearly complete turnover of personnel; (*c*) trainees were received from recruit training centers, several of which had a high incidence of streptococcic infections; (*d*) the schools were located in an area where the climate in winter is favorable for the dissemination of streptococcic infection.

The epidemiologic picture at the three schools was considerably different from that seen in more static populations. The repeated introduction of susceptible individuals produced winter-long epidemics, which varied with the degree of infection at the training centers whence the trainees came and also with the local epidemic situation in the school into which they came. Instead of a curve rising to a peak and then gradually decreasing, the epidemic curve at the schools being discussed was represented by a series of peaks occurring late in the training period of each group of trainees, the level of the curve and the magnitude of the peaks becoming progressively higher during the winter.

In November 1944 rising streptococcus morbidity rates led to the institution of sulfadiazine prophylaxis. In each school the first period of chemoprophylaxis was successful, significantly fewer streptococcic infections occurring in the groups receiving prophylaxis than in the control groups. During this period sulfadiazine resistant streptococci were not recovered in one school and were present in small numbers in the other two.

The second period of chemoprophylaxis with new trainees resulted in a progressive failure to prevent streptococcic infections in the treated group. This failure was related to the increasing prevalence of strains of group A hemolytic streptococci which showed in vitro resistance to sulfadiazine.

The question of the mechanism of drug resistance is controversial. It is not known whether it represents a genetic mutation occurring spontaneously in nature, the mutants being selected for survival because of their ability to withstand the presence of the drug, or whether the drug itself induces a change in the organism by direct action. Regardless of which of these happens to be correct, the resulting epidemiologic problems are the same, once resistant strains occur.

It is a matter of considerable interest, however, to know how frequently streptococci become resistant to sulfonamides, and unfortunately it is impossible from the data at hand to make a reliable estimate of this. In the epidemics which have been described here it is impossible even to say whether the resistant strains which became prevalent acquired their resistance locally or were imported from a naval training center where resistant strains of the same types were known to have existed and from which drafts of men were frequently received. The number of men from that training center constituted from 1. to 5 per cent of the total trainees, and drafts had been received from there during the six months preceding this study. The appearance of resistant strains at each of the schools was preceded by the arrival a week to ten days previously of drafts of men from that training center. It is quite possible that some of these men were carriers of resistant strains. (To establish the possibility of this origin of the strains, cultures were taken of 58 men from that training center on arrival. Twenty [34 per cent] were found to be group A hemolytic streptococcus carriers, 9 [16 per cent] were carriers of types 3, 17 and 19, and of five of the latter strains tested, two were sulfadiazine resistant in vitro.) If one postulates the introduction of resistant streptococci by these men, one is confronted with the question of why the strains were not recovered during the period prior to chemoprophylaxis and were present in such small numbers during the first period of chemoprophylaxis. This question cannot be answered with any degree of certainty. It may be that the strains were actually present in small numbers during the early part of this study and did not spread at that time because of the absence of epidemic conditions. The possibility, however, that the resistant strains encountered here were not derived from existing strains but acquired resistance during chemoprophylaxis cannot be denied.

The question of the duration of resistance in a particular strain is also one which cannot be answered by data at hand. Four months after the termination of chemoprophylaxis in the three schools under discussion, resistant strains of types 17, 19 and 3 were still prevalent. However, this does not necessarily mean that the strains were the progeny of those previously encountered, for during those four months more than 90 per cent of the trainees received came from a training center at which these strains had become prevalent.

CONCLUSIONS

1. Sulfadiazine given in daily doses of 1 Gm. effectively prevented acute respiratory infections by group A beta hemolytic streptococci in the absence of sulfadiazine resistant organisms in three small naval training schoools.
2. Sulfadiazine prophylaxis became progressively less effective as strains showing in vitro resistance to the drug became prevalent.

THE TREATMENT OF COMPOUND FRACTURES OF THE FEMUR

LIEUTENANT COLONEL RALPH SOTO-HALL
and
LIEUTENANT COLONEL THOMAS HORWITZ
Medical Corps, Army of the United States

War offers an unexcelled opportunity for the observation and study of compound fractures. From diverse theaters of war a large number of these injuries, which were originally treated by other surgeons, are finally brought under uninterrupted supervision with almost ideal hospital facilities so that the results of different methods of therapy can be studied and compared. Under these conditions, impersonal conclusions can be reached which are not hampered by the unavoidable human optimism that may cloud the opinion of the proponent of some particular method of treatment.

This injury is a serious surgical problem. In World War I the record shows a total of 5,138 compound fractures of the femur with a mortality in the vicinity of 23 per cent and with a permanent disability of more than 50 per cent in 48 per cent of the cases (fig. 1).

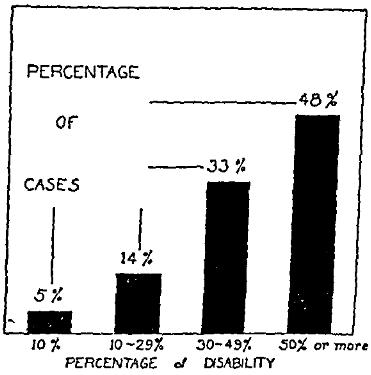

Fig. 1.—Rating for disability in the 5,138 fractures of the femur in World War I.

Our object in this study is to review the late results of 163 fractures of the femur and to formulate conclusions against the background of our own experience in two separate theaters. The series includes 117 compound fractures, of which 17 had been treated by early internal fixation. To obtain the proper standard for comparative study, 46 simple fractures are included, of which 24 had been treated by early internal fixation. By inclusion of these four groups (table 1) we hope to throw some light on the etiology of such complicating factors as sepsis, nonunion, deformity and knee stiffness.

Of the 41 fractures treated by open reduction with internal fixation, 36 were fixed by a six-screw plate and 5 by multiple transfixion screws alone. In the 122 fractures treated by traction-suspension alone, skeletal traction was secured by Kirschner wire or Steinman pin inserted in the distal end of the femur or proximal end of the tibia, depending on the level and nature of the fracture. The extremity was suspended in the Keller-Blake half-ring splint with Pierson attachment and balanced by adequate weight, the knee being kept in varying flexion, 15 to 30 degrees. This treatment was begun in the theater of war and usually, when callus formation appeared to be adequate, these fractures were immobilized in a 1½ plaster spica and the patients were transported to general hospitals in the zone of the interior. On arrival, immediate attempt was made to change these patients back to a traction suspension splint. In general, transportation has led to very few difficulties or complications except in rare cases which were transported at a period when the fracture site was not solid enough.

Paper published under the auspices of the Section on Orthopedic Surgery.

Although disagreement often occurs regarding technics of treatment, there is complete concurrence in what the primary ideal goal should be—to convert a compound fracture into a simple fracture, an open into a closed fracture. That method which produces the earliest healing of the wound is ultimately the most successful, for skin is the only covering which protects human tissue from such enemies as infection or thermal changes. It is the protecting shield given by nature to safeguard the deeper tissue from damage. The history of wound treatment in the past is an incessant search for wound cover by a multiplicity of methods which attempted to substitute chemical substances, dressings or plaster for this normal shield.

The initial and most vital factor in preparing a compound wound for ultimate closure is complete and thorough débridement performed at the earliest possible time after injury. No change in this opinion has been caused by modern chemotherapy. The operation should consist in excision of the contaminated skin border and removal of all devitalized tissue and of all small fragments of bone which are completely unattached. Removal of very large bone fragments, often making up whole segments of the shaft, is not indicated because they often become revascularized, and, if removed, they create a serious problem in late reconstruction. The hand of conservatism is further strengthened by the fact that large bone fragments, when they do sequestrate, are easily removed after they have served as a bridge for new bone formation. Metallic foreign bodies which are readily accessible should be taken out, but a tedious search for inaccessible small fragments is not advisable unless they lie within a joint cavity. It is remarkable how little bother these multiple shell fragments produce, although a relatively infrequent but important number of cases in which they lead to arterial aneurysms or arteriovenous fistulas must be kept vividly in mind. On the other hand, nonmetallic radiotransparent foreign bodies have been, in our experience, an annoying source of infection and persistent drainage. In these cases we have found as offending agents pieces of clothing, leather and even parts of rubber heels.

The element of time is one of the essential factors in the success of débridement. Cases in which operation was performed within the first twenty-four hours gave a higher percentage of success, as shown in table 2, which includes patients treated without the introduction of any type of internal fixation. The latter were purposely excluded, as they would have confused the issue with new problems.

Although local factors may alter the situation, the advisable surgical procedure after forty-eight hours seems to be wide incision for drainage and the removal of any large masses of necrotized tissue, rather than a formal débridement.

After successful débridement the selection of a method of treatment offers many alternatives, the main ones being (1) closed plaster technic, popularized in its original form in this country by Orr, (2) the Carrel-Dakin technic, (3) surgical closure of the wound by (*a*) primary suture, (*b*) free skin graft, (*c*) delayed closure. The closed plaster technic has the advantages of ease in handling and comfort in transport. It avoids new bacterial invasion because of infrequent dressings and clears up dead tissue by the proteolytic effects of bacteria. A material benefit from this method is the localization of infection by complete splinting. Against these advantages are the obvious adverse factors of healing with large adherent scars, which often mat down muscles, fascia and nerves; the chronic absorption of toxins with resulting toxemia, the loss of protein from chronic exudate, and especially heavy scar formation with delayed healing, leading to an unavoidable delay in the performance of reconstructive surgery. The field of application of this method is still large, because many wounds are too extensive to be closed, and its value in transportation makes its use imperative. However, we do not believe that large wounds treated by this method should be allowed to go unaided with resultant formation of a large contracting scar, but that instead the wound should be vigilantly watched for the opportunity to close it or reduce its size by the use of a free skin graft, skin flaps or, if necessary, ostectomy. The Carrel-Dakin method of chemical irrigation, although no longer used as a method complete in itself, is still of great value as a procedure for the preparation of wounds, and we have not infrequently taken advantage of it to free a wound of minor necrotized tissue and superficial sepsis in preparation for some secondary closure.

Primary suture has been widely used in civilian practice, offering a brilliant method of rapid transmutation of an open into a closed fracture. It is particularly useful in fractures compounded from within or those presenting little injury to soft tissue, but in the large wounds both in civilian life and in war surgery the hazard of an occasional infection, principally of an anaerobic type, leading to loss of life or limb, creates a need for a safer approach to the problem. To circumvent this hazard, surgeons started covering the wounds immediately after débridement by large free split thickness skin grafts which were loosely sutured as a wound dressing. This procedure often gives brilliant results (fig. 2), although at times the plastic removal of adherent skin at a later date may be necessary. One of us (R. S.-H.) used this method in a number of recent air war wounds and found it free of danger. The method should always be considered when the surgeon is confronted with a wound area too large for secondary closure.

Realizing that early closure of the wound and prompt establishment of function was desirable, certain surgeons toward the end of the last war cautiously began to carry out delayed primary suture and secondary suture. This was done, however, with the ever present fear of stirring up severe infection, particularly of the anaerobic type, and in the history of the last war[1] it was strongly emphasized that "cooperation of a bacteriologist is indispensable in making the decisions as to the indications for delayed primary or secondary suture." On the other hand, surgeons in this war have taken up with enthusiasm this secondary operation, and their almost unanimous opinion seems to be that bacteriologic reports are no longer of definite importance but that the clinical appearance of the wound is the deciding factor. This difference of approach to the same surgical goal comes in part as a result of the use of modern antibacterial agents, which have removed the hazards from these procedures. It should be emphasized, however, that neither penicillin nor the sulfonamide drugs should be used with unbounded confidence as prophylactic remedies because, as has often been stated, they are ineffective in the presence of devitalized tissue; so that closure should not be attempted when this is present.

---

[1] Ireland, M. W.: The Medical Department of the United States Army in the World War, Washington, D. C., Government Printing Office, 1927, vol. 11, pp. 304-314.

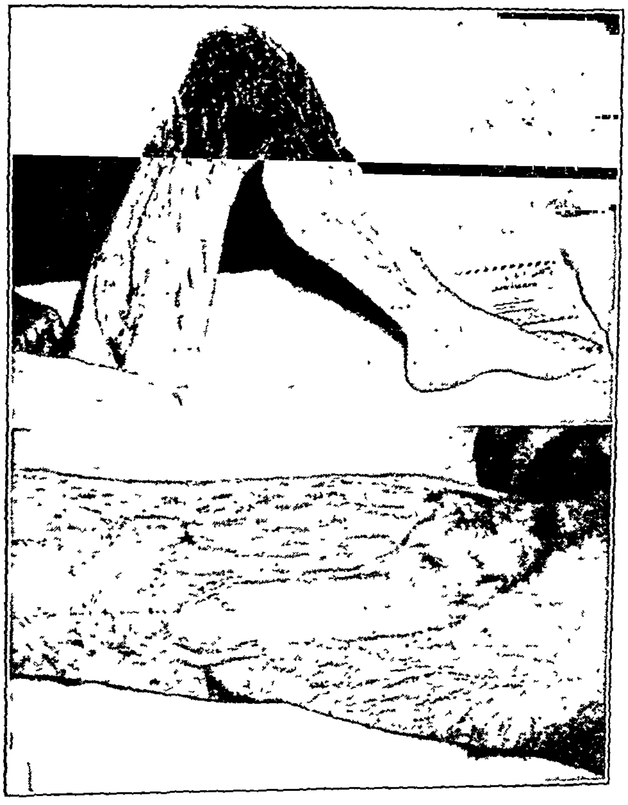

Fig. 2.—Patient was wounded Oct. 2, 1944 in France, when he stepped on an antipersonnel mine. He had immediate débridement. There was loss of about 50 pe[illegible] muscles. October 16 in a general hospital in [illegible] he had the skin graft, which healed. Flat [illegible] hs after large wound had been covered with a split thickness [illegible] lent range of knee motion.

Delayed primary suture is defined as that procedure in which the edges can be approximated without excision and will then heal, whereas, in secondary suture, excision of the granulation tissue and of the whole wound is necessary for successful healing. The procedure is similar to that used for excision of an ulcer. The stage of repair of the wound and therefore the time factor determine the type of procedure to be used. In the period of time between débridement and the performance of delayed closure the wound should be left freely open with a gently placed pack of plain or petrolatum gauze, and the fracture should be well splinted. The most ideal period for delayed primary closure of femoral fractures appears to be between the seventh and the twelfth day. Table 3 is not in itself conclusive evidence but does confirm our clinical experience.

It is not our purpose to discuss the technical details of delayed closure, which have been fully described in the recent literature, except as they may be seen to have effect on the late results. The brilliant work of Churchill,[2] Lyons [3] and Hampton [4] has emphasized the importance of adequately preparing the local factors as well as the systemic factors for this procedure. Restoration of total blood protein and of a normal hematocrit and red cell count plus the avoidance of a vitamin C deficiency have all been shown to be of importance. Local factors leading to successful closure are an approximation of the tissues without tension, proper splinting and the avoidance of dead space, plus good hemostasis. Among the most serious infections we have seen are those in which the last two principles have not been observed. In all cases in which the control of bleeding is in doubt or in which there is dead space posterior counter drainage should be instituted, for otherwise this leads to an infected blood clot or abscess formation with subsequent death of bone. Counter drainage for a period of two to three days seems to us to be indicated for a large proportion of cases. When successful delayed closure has been obtained, the general condition of the patients has been excellent and locally there is a firm and supple scar which allows early remedial exercises and which also permits the performance of reconstructive surgery much sooner.

INCIDENCE OF INFECTION

A very high proportion (29 per cent) of compound fractures without internal fixation healed without sepsis. When this group is added to the 44 per cent which healed within two or three months and which we have classified as mild infection because they represented mainly soft tissue sepsis, the whole picture presents a brilliant achievement of war surgery. The infected group (27 per cent) includes many cases of extensive loss of soft and bone tissue with vascular damage in which sepsis is almost unavoidable (fig. 3). Of those cases treated by early internal fixation through an open wound, a total of 19 were seen by us, 17 of which are included in this study. In these the incidence of severe sepsis was about 50 per cent higher than in patients treated without metal fixation. In most of these men the plates or metal had to be removed. An almost identical finding was noted in the series of compound fractures of other long bones treated by early metallic fixation, which we now have under study, with the exception that in the tibia the prognosis seems to be somewhat worse than in the other bones. Of particular interest is the fact that in some cases severe infection seemed to be under control for several weeks while chemotherapy was being administered, manifesting little local or general reaction but later became clinically evident. This factor may explain the enthusiasm of some surgeons in the forward areas who have not had the opportunity to follow the later phases of the problem. Two illustrative cases are the following:

---

[2] Churchill, E. D.: Surgical Management of Wounded in Mediterranean Theater at the Time of the Fall of Rome, Ann. Surg **120:** 268-283 (Sept.) 1944; Bull. U. S. Army M. Dept., January 1945, No. 84, pp. 58-65.

[3] Lyons, C.: The Philosophy of Wound Management in the United States Army, Bull. Am. Coll. Surgeons **30:** 13-14 (Feb.) 1945.

[4] Hampton, Oscar P., Jr. Personal communication to the authors.

Patient 1, wounded by a shell fragment Oct. 14, 1944, sustained a slightly comminuted compound fracture. October 14, within twelve hours, débridement of the wound and application of a spica cast were done. On October 22 secondary closure of the wound was done and through a separate incision the fragments were fixed together by four metallic screws. No counter drainage opening was made. The patient received penicillin from the date of injury to the date of secondary closure, and penicillin was continued postoperatively for several weeks. On arrival at the zone of the interior in January 1945 he presented profuse drainage, a temperature of 104.10 F. and a large abscess in the postlateral part of the thigh which necessitated surgical incision. On February 12 the screws were removed. Despite severe infection and drainage the fracture was felt to be united on February 11, although a large area of bone had sequestrated. Further surgery will be needed.

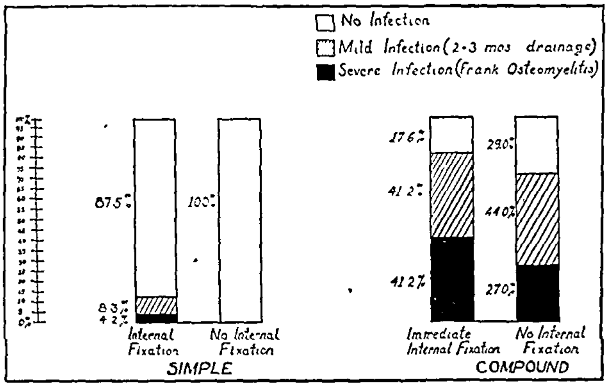

Fig. 3.—Incidence of infection in fractures of the femur. Under internal fixation in the compound group are included cases which had been plated within the first month, either in the presence of an open wound or within two weeks of its closure.

Patient 2, aged 27 years, was struck by a shell fragment in the right lower thigh March 2, 1944, sustaining a compound comminuted fracture of the left femur and wound of the right thigh. On March 5 gas gangrene appeared in the right thigh and midamputation was done. On March 19 operation was performed on the patient and a metallic plate was placed in the left femur in the presence of an open wound. No counter drainage was employed. Traction was used following the operation until March 25, when a left hip spica was applied. On June 15 a large abscess of the left thigh was incised and drained. The right stump healed in five weeks. X-rays on August 15 showed an extensive comminuted fracture of the left third of the femur with obvious osteomyelitis, and many sequestrums could be distinguished. Because of persistent drainage of the left femur on September 12, a sequestrectomy was done and the plate was removed. This led to reduction in drainage and increased comfort of the patient. Penicillin was used before and after operation for several weeks.

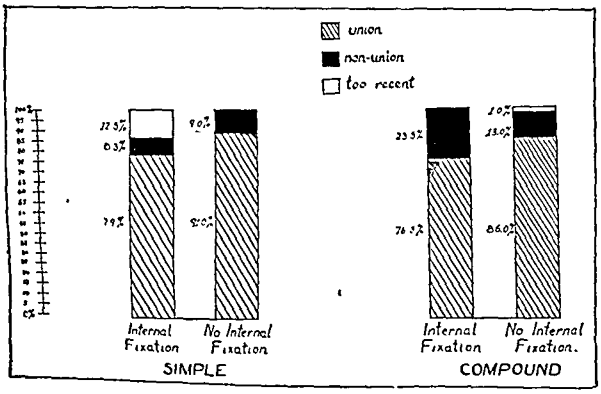

Fig. 4.—Incidence of nonunion in fractures of femur.

In this series, cases treated by internal fixation have been done at various stages and with some difference in technic. The operation has been done at times immediately after injury through the compound wound or after closure of this wound by immediate fixation through a separate incision or, lastly, delayed a few days until the wound has healed. The best results and the procedure which seems to us to offer the least danger for that type of fracture wherein internal fixation appears indicated consisted in the following sequence: A thorough débridement was done early, and this was followed by delayed closure of the wound, performed about seven to ten days later. After healing of the original wound (an average of sixteen days) the fragments were approximated through a separate longitudinal incision and held together by metal fixation. When the type of fracture allows, the use of screws has given better results than the plate, probably because of the lesser surgical trauma. As previously mentioned, a small counter drainage incision may be advisable.

EFFECT OF CHEMOTHERAPY

Seventy-three cases of the total 100 compound fractures treated without internal fixation had adequate record of the use of chemotherapy. This included both penicillin and a sulfonamide compound or both. Locally the sulfonamide drug had been used almost universally as a first aid, but we have felt that an evaluation of its use could not be made in the zone of the interior and have included in the group only cases of adequate systemic administration. These findings again prove the fact that modern antibacterial agents may produce excellent results in controlling infection and in reducing complications but that they are impotent in the presence of tissue which has lost its blood supply and which does not allow the drug to come in contact with infection.

Table 4.—*Study of Effect of Antibacterial Agents in 100 Cases of Compound Fractures of Femur*

	Total	Recorded Use of Anti-bacterial Agents	Sulfon-amides	Penicillin	Sulfon-amide and Penicillin
Clean..............	29	24	3	7	14
Mild..............	44	28	7	12	9
Severe..............	27	21	1	4	16
	100	73			

The effect of antibacterial drugs is shown in table 4.

INCIDENCE OF NONUNION

For the purpose of standardization, five months has been used as the period of time considered normal for the completion of bone healing. When union occurred between five and seven months it was classified as delayed union, whereas cases which showed neither clinical nor radiologic evidence of bone union beyond seven months were classified as having reached the stage of nonunion. In a few instances, however, such as in the absence of a large segment of bone, the diagnosis of nonunion was made earlier. For simplicity of demonstration, only the nonunion cases are shown in the graph. Considering the frequency of severe injury with comminution and absence of bone fragments, the proportion of bone union in the cases treated by external splinting was extremely high, 86 per cent. This was definitely higher than the finding in fractures treated by internal fixation. A comparison of the behavior of union in simple fractures treated both by open and by closed reduction seems also of value, because it demonstrates that in spite of the improved apposition of fragments in the open cases there is little difference in the period needed for bone healing (fig. 4).

The state of delayed union and of actual nonunion appears directly related to degree of bone loss or damage, distraction and the presence of infection, particularly of a severe type. Distraction, even of a very minimal amount, is particularly harmful. To avoid separation of fragments due to excessive weight, we believe that a very satisfactory way of handling the Thomas splint is to reduce the fracture manually and then use the traction suspension as a method of holding the reduction rather than of producing traction. There are, in addition, certain mechanical factors existent in instances in which internal fixation has been employed. The immediate effects of the foreign body are often gratifying, such as restoration of axis alinement and of end to end approximation. The delayed effects may be vicious: (*a*) Distraction appears to be a paramount influence. This distraction interval appears late and is due to actual resorption at the bone ends, a normal finding in the process of fracture healing. This factor is eliminated in transverse fractures in which no rigid device is employed, internal or external, and in which the bony ends may continue to approximate, as they may in traction suspension; nor is this factor dominant in oblique fractures, which lend themselves so well to multiple screw transfixions. (*b*) There is occasional loosening of plates and screws. (*c*) Failure of callus formation occurs on the side adjacent to the foreign body, which is strikingly evident in many cases in which callus appears abundantly on all sides of the fracture. This failure of callus formation, and the persistence of the fracture gap on the side of the plate, are difficult to explain, since in no instance in which plates have been removed (in simple, uncomplicated fractures) has there been any evidence of actual untoward reaction of the body tissues to the stainless steel foreign body.

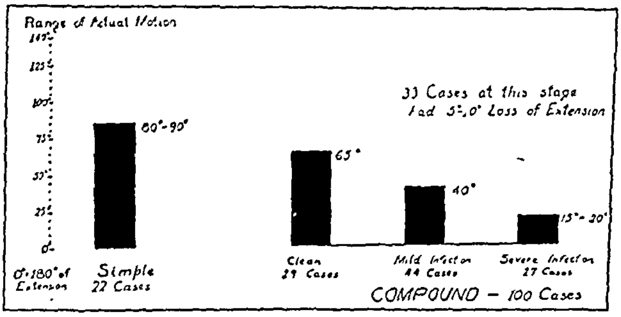

Fig. 5.—Average range of knee motion in fractures of femur nine and a half months from date of injury.

OTHER COMPLICATIONS

Refracture.—Five patients sustained a refracture during convalescence. This reinjury occurred on an average of seven and one-half months from the original accident and roughly about five to six weeks from the beginning of ambulation. The application of the Thomas caliper splint during the early stages of convalescence has been obligatory in the service, but this complication illustrates how ineffectual such a splint may be in injuries occurring in the upper half of the femur. In fact, it may at times act as a lever throwing the point of greatest stress at the fracture site. To increase the efficacy of the splint we have increased the angle of tilt of the ring so that its outer part is above the trochanter. Because of the tendency to angulate and refracture at this high level, a period of suspension with exercise should be carried out for three to four weeks beyond the time when clinical union is apparent.

Renal Lithiasis.—In this series 6 patients have shown clinical evidence of kidney stones, which usually appeared as the patient became ambulatory. Although this incidence seems high, it does not give a true picture of the frequency of urolithiasis in femoral fractures. Russel and Smith[5] of this service command have carried out routine radiographic investigations in 50 consecutive femurs and have found that 8 of these men presented radiographic evidence of renal calculi. The prevalence of this finding during the long period of recumbency needed in the traction suspension treatment suggests that through inadequate fluid intake and gravity stasis there is improper renal drainage, so that particular care should be taken to keep the fluid intake at a high level, to create postural changes and to give abdominal exercises. Repeated urine examinations are indicated in all cases under traction treatment. Widespread use of sulfonamides may play a part, although these stones to date have failed to show any evidence of the drug. Fractures of the long bones of the arms which are ambulatory do not have this complication, suggesting that increased calcium output is not the answer.

Knee Motion.—Considering the fact that, because of military reasons, this series represents a very young age group, the restoration of knee function represents one of the most disheartening problems that we have had to face. The whole problem of knee stiffness is a very complex one and offers a challenge which we have failed to meet. Two factors which are definitely helpful have been, however, the use of resistive exercises and the use of delayed closure.

In this series the average period from the date of injury to the last examination was only nine and one-half months, so that unfortunately the statistics do not tell the complete story of the end results but do describe the slowness in restoration of joint motion. A later review of these cases should be made. Successful delayed closure has brought about much earlier healing and less scarring, so that exercise and activity can be started earlier, leading to better function. An attempt to separate the results of the men treated by internal fixation or by traction showed no appreciable difference. The findings were not entirely conclusive because a number of the patients who had had sepsis or delayed union had too recent splinting. For that reason the groups were classified as noted in figure 5.

In the pathology of knee stiffness many factors are included. There is often a matting of the quadriceps at the site of injury, leading to a checkrein effect. Frequently there has been an acute synovitis with effusion which is followed by secondary matting of the quadriceps pouches, and not infrequently we have noted traumatic degeneration of the articular cartilage of the patella, the so-called chondromalacia. All these pathologic changes lead to a secondary capsular contraction with intra-articular adhesions.

---

[5] Russel, Stuart W., and Smith, Louis D.: Personal communication to the authors.

No difference has been noted in the knee motion between cases treated by skeletal traction in the lower end of the femur or in the upper end of the tibia, with the single reservation, however, that femoral pins are at times improperly placed so that it would seem reasonable that the less experienced surgeons should use the tibial site.

An important disability is the limitation of extension of 5 to 10 degrees, which is noted in about one third of the cases. This is usually an active loss of motion but may also be passive. We attribute this finding to the treatment of the knee for a long time in a position of flexion, a position which does not allow the vastus medialis to come into a normal function. In this prolonged position of flexion the intra-articular structures may also become temporarily adherent and produce the passive restriction. This disability can be corrected after several weeks of active exercise, but its presence argues in favor of treatment of fractures above the lower third with the knee in full extension.

PHYSICAL THERAPY

Exercise therapy of the thigh muscles should be started as soon as the wound is healed. Static exercises, such as quadriceps setting, can be done in a Thomas splint suspension or in a plaster spica. These exercises should be repeated throughout the day and should be done with considerable force in order to be efficacious. Remedial exercises should at first be given to correct the atrophy and later to produce agility, coordination and endurance. It is important to separate these two phases and to maintain in one's mind the important principle that exercise therapy must have resistance to produce power and hypertrophy, and repetition of movement to lead to endurance. Application of exercise on this basis has led to the most encouraging results that we have seen. In this command Capt. Thomas DeLorme[6] has applied the paraphernalia of professional weight lifters, consisting of an iron boot with attached bar bells, in order to produce resistive exercises for these femoral fractures. This has led to a remarkable increase in muscle power and in stability of the knee, with a secondary increase in joint motion. This change from the passive to active exercise offers hope for the future, when thigh muscles are seen in the injured side which may at times have a greater circumference than those of the normal thigh. Because of the ability to introduce exercise therapy so much earlier, cases which have had a successful delayed wound closure result in better function.

CONCLUSIONS

1. Early and adequate débridement is the most vital factor in the successful treatment of a compound wound.
2. Modern chemotherapy has not altered this opinion, although the use of bacteriostatic drugs has brought brilliant results in controlling the invasive infection and in reducing the number and severity of complications.
3. The principle of converting an open fracture into a closed one by delayed wound suture is strongly endorsed because it insures, with minimal hazard, rapid healing and little scar formation.
4. Conservatism in removal of large bone fragments is advocated, since it lessens major problems of reconstructive surgery.
5. An analysis of 163 fractures of the femur treated in various theaters of war indicates that extremely gratifying results are being obtained with the conservative treatment of traction in balanced suspension. There has been a low incidence of sepsis and a high percentage of bone union without deformity.
6. The use of early internal fixation in the presence of an open wound is accompanied by greater danger of complication. When indicated, in a few selected cases, internal fixation is safer if performed soon after the healing has been completed following secondary closure. The operation should be performed through a separate longitudinal incision with temporary counter drainage. When the type of fracture permits, multiple screw fixation is superior to the use of plates because of lessened surgical trauma.
7. The early use of active exercise, with carefully supervised resistive exercise during convalescence, offers a hopeful opportunity for the improvement of knee function.

350 Post Street, San Francisco.

ABSTRACT OF DISCUSSION

DR. GUY A. CALDWELL, New Orleans: This review by Lieut. Cols. Soto-Hall and Horwitz of the late results obtained in 117 compound fractures of the femur sustained in battle contains several lessons which have been emphasized by research and experience in civil hospitals during the war. It has been shown by the National Research's Council's Subcommittee on Infected Wounds and Burns that major emphasis must be placed on adequate, well timed surgical measures rather than on chemotherapy in the care of compound fractures and that plating of the fracture through an open wound materially increases the danger of serious infection. In civil life the patient may reach the hospital so promptly that definitive operation may be done in less than three hours, and it often is possible to close the wound primarily and without tension. The temptation to use internal fixation under these conditions is great. However, the late results in cases so treated in our service at Charity Hospital in New Orleans over a period of two years have been so discouraging that we have almost abandoned the use of plates and screws in compound fractures. We are finding also that, when tissue damage is great, gross contamination is apparent and closure difficult, it may be the shorter road to early healing to leave the wound open and close or graft it secondarily. Although the total number of fractures occurring each year in America is comparable to those occurring in battle casualties, they are so widely scattered that they cannot be concentrated in a few special centers. The tendency to transport the patient to the nearest hospital regardless of its facilities or its surgeons' ability has always contributed to the poor results. Free choice of a physician by the patient certainly is desirable, but the desirability is predicated on the assumption that all physicians are equally competent to treat every condition or are fully conscious of their limitations and will promptly refer the patient to a competent specialist. Not until every physician learns to recognize and refer serious fractures to competent centers and not until the surgeons in those centers nominate and support the best qualified men to supervise their fracture services will the results of fracture treatment in civil practice approach those realized in this war.

DR. J. ALBERT KEY, St. Louis: This paper again indicates that the Army is obtaining satisfactory results with the traction suspension method of treatment of fractures of the femur which it has adopted as standard. I agree with early débridement and that the wound should be closed *only* when the surgeon can observe the patient until danger of infection has passed. The delayed primary or early secondary closure of the wound and the covering of large wounds by split skin grafts when the skin cannot be closed because of tension are valuable procedures. The skin graft acts as a sterile dressing. From this paper I am not able to determine the relative value of sulfonamides and penicillin or even whether they influenced the incidence and extent of infection. This is because no two cases are alike. Not only do wounds vary, but also the contamination and the resistance of patients vary. Consequently, one should not condemn the use of internal fixation in all compound fractures. It is quite possible that the increased incidence of infection resulted from severe wounds when internal fixation was indicated as a life saving measure. In civilian practice in the hands of competent surgeons, modern internal fixation combined with chemotherapy and adequate external fixation is a relatively safe and effective method of treating selected compound fractures. This series confirms previous knowledge that traction methods of treatment are just as effective in obtaining union as are open reduction and internal fixation. The incidence of refracture seems rather high. This is partly due to the use of the Thomas caliper walking splint in convalescence. This gives a sense of false security and may result in refracture or bowing. The patient should remain in bed after traction is released and exercise his limbs against gravity and resistance until union is solid enough for crutch walking. Conclusions as to stiffness at the knee will be modified later, as this stiffness will lessen with use. The limitation of extension could be lessened by placing skin traction on the lower part of the leg with the knee straight for a short time while the fracture is consolidating and after union has been obtained but before the patient has been got up on crutches. Traction and suspension is not the only method of treating fractures of the femur, and in civilian life the surgeon should use the method which gives the best results in his hands. An example of this is the brilliant results obtained by manipulative reduction and immobilization in a plaster of paris spica cast in the hands of the late Willis Campbell.

[6] DeLorme, T. L.: Muscle Development of Use of Heavy Resistance Exercise, to be published.

Dr. Ralph Soto-Hall, San Francisco: Dr. Caldwell's remarks emphasize well the parallel progress that has taken place in civilian and military practice through the years of the war. His conclusions relative to chemotherapy, débridement and plating of compound fractures concur with our military experience. Colonel Horwitz and I feel that the great margin of safety resulting from handling cases with secondary closure will not be readily given up in the future in civilian hospitals for the treatment of severely contaminated and badly lacerated wounds. Why close a severe compound wound in a few hours with risk and hazard when it can be done in a few days practically without peril? The Army has made an effort to concentrate its well trained personnel. The treatment of compound fractures by internal fixation has been confined largely to specially selected installations, leading to an extensive experience for the personnel. For this reason our impartial evaluation is significant because, if a greater percentage of infection and nonunion will occur in the hands of experienced men, certainly we must expect a dismal outlook when plating of compound fractures is performed by less qualified surgeons. Dr. Key has suggested that the increased incidence of infection in these cases might have resulted because of more severe wounds. Actually this did not occur in our series because these cases presented no greater severity of wound or complication than those treated by the traction method. Knee motion, as he has suggested, has increased with time, but the progress has been slow, the problem is still unsolved and we must seek new methods of approaching this complication.

Intracerebral Hemorrhage.—Hemorrhages into the substance of the brain in patients with injuries to the head usually develop at the time the blow is sustained and are due to laceration of cortical or subcortical vessels. Rarely the hemorrhage may have its onset several days after the injury. The cause of these so-called "late hemorrhages" is not clear. The differential diagnosis between traumatic subcortical clot and extradural or subdural hematoma cannot be made without operation. Evidence is accumulating that operative removal of the intracortical clot is feasible and is followed by marked improvement in the patient. Delayed onset of hemiplegia may also occur as the result of thrombosis of cerebral vessels consequent on incomplete tearing of their coats.—Merritt, H. Houston; Diagnostic Considerations in Patients with Head Injury, in Trauma of the Central Nervous System. Baltimore. Williams & Wilkins Company, 1945.

MEAT IN THE DIET OF PREGNANT WOMEN

RUTH M. LEVERTON and THELMA J. McMILLAN
Lincoln, Neb.

The importance to both mother and child of adequate protein intake during pregnancy has been well established. The medical and nutritional aspects of the problem have been reviewed recently by Williams[1] in The Journal. Numerous and thorough studies of the diets of pregnant women reviewed by him indicate, however, that the protein intake of these women seldom equaled the National Research Council recommendation of 85 Gm. daily and that it was less than 60 Gm. a day in about 50 per cent of the cases.

The purpose of the study being reported was to test the effectiveness of a simple dietary recommendation that could be made to the patient by the physician, whether family doctor or specialist, and which if followed would insure an increased protein intake for the pregnant woman, especially the one with anemia.

The dietary recommendation selected for test was "Eat plenty of meat—have a generous serving at least twice a day." The reason for the choice of this particular recommendation lay in the fact that (1) the quantity and quality of protein of meat make it a superior food source of this dietary essential and therefore the size of servings recommended need not be incompatible with any individual's capacity for food, (2) meat contains a liberal assortment of nutrients other than protein, (3) meat rates high in appetite appeal and consumer acceptability, (4) meat is procured at the food market rather than at the drug counter and (5) there is a widespread misconception that women should not eat much meat, especially during pregnancy.

The women who served as subjects for the study were secured through the cooperation of local obstetricians. All were private patients of adequate economic status, had histories of generally good health and were under 33 years of age; all of them thought they were following their physician's advice "to eat a good diet"; the majority of them were receiving additional vitamin A and D and calcium phosphate.

To insure that the women were receiving "plenty of meat," they were supplied with a 5 ounce serving of lean meat daily (three fourths of the time it was beef). They ate this supplementary meat in addition to their self-chosen diets and at times other than the main meal (which usually included meat). The meat was bought by the laboratory in large quantities, cut into individual servings, wrapped, frozen and stored. Deliveries were made to the women once or twice a week, depending on their home refrigerator storage space.

For each woman thus supplied with meat there were two experimental partners, women of approximately the same age, who had had the same number of children, if any, were at the same stage of pregnancy and whose blood had the same hemoglobin value. One partner received daily a vitamin B complex supplement which furnished in capsule form 2 mg. of thiamine, 1 mg. of riboflavin, 20 mg. of niacin and small amounts of other factors of the complex. The other partner was a negative control and received no supplement.

The supplements of meat and vitamin B complex were begun early in the fifth month of pregnancy and

This work was supported by a grant from Swift and Company. Obstetricians of Lincoln cooperated by providing patients for this study. Published with the permission of the Director as Paper No. 389, Journal Series, Nebraska Agricultural Experiment Station.

[1] Williams, P. F.: Importance of Adequate Protein Nutrition in Pregnancy, J. A. M. A. 127: 1052 (April 21) 1945.

continued for three months after delivery; the control member of each trio was studied for the same length of time. Each woman kept a record of her food intake for one week during the eighth month of pregnancy, and from this was calculated her protein intake.

The effectiveness of following the "eat meat" recommendation as compared with receiving the B complex supplement and with receiving no supplement was measured by determination of the hemoglobin and red cell content of the blood at monthly intervals. The hemoglobin level was considered a good index to use, because low hemoglobin values during pregnancy have been shown by several workers to be associated with suboptimal protein intakes. A low hemoglobin level warrants attention even though not all cases of anemia in pregnancy present the same blood picture or indicate the same deficiency. Hemoglobin in the venous blood samples was determined by the method of Todd and Sanford and the fully developed oxyhemoglobin read in a Sanford and Sheard photelometer.

More than 75 women, or twenty-five sets of three women each, began as subjects for the study in 1942-1943, but less than half of them completed it. The chief reason for discontinuing a subject was that the women moved away when the husbands were drafted; only a few women had to be discontinued because they were not consistently cooperative or because their families objected to the monthly blood tests.

Results are reported for 33 women, or eleven sets of matched partners. In the table are given the average values for hemoglobin and red cell count for each group at monthly intervals from four months before until three months after delivery. These values are shown graphically in the chart. They were calculated in terms of the percentage of the value at the beginning of the study, i. e. the initial hemoglobin or red cell value for each subject was assigned a value of 100 per cent and every succeeding value was calculated from this base line.

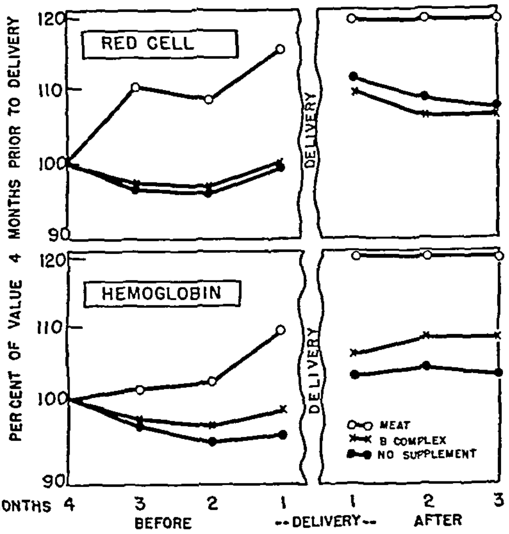
The women who received the additional meat had consistently better hemoglobin and red cell values at all times than did their experimental partners who received either B complex or no supplement. The values for the latter two groups were similar, although the B complex group had a slightly higher hemoglobin level, especially after delivery.

Comparison of Hemoglobin and Red Cell Value of Groups of Women Receiving Meat, B Complex or No Supplement

	Months Before Delivery				Months After Delivery		
Supplement	4	3	2	1	1	2	3
Meat							
Hemoglobin, grams	10.7	10.9	11.1	11.7	12.8	12.8	12.8
Red blood cells, millions	3.8	4.2	4.1	4.4	4.6	4.5	4.5
B complex							
Hemoglobin, grams	10.7	10.5	10.4	10.6	11.4	11.6	11.6
Red blood cells, millions	3.8	3.7	3.7	3.7	4.2	4.0	4.0
None							
Hemoglobin, grams	10.8	10.5	10.3	10.4	11.2	11.3	11.2
Red blood cells, millions	3.7	3.6	3.6	3.7	4.1	4.0	3.9

One month prior to delivery the women who had had extra meat for three months had an average increase in hemoglobin level of 10 per cent and of 16 per cent in red cell count. At the same time the values for the women who received B complex were 99 per cent for hemoglobin and 100 per cent for red cell count and 95 per cent and 100 per cent respectively for the controls. The protein content of the self-chosen diets at this time averaged 58 Gm. daily for each group of subjects. The additional meat contained 25 Gm. daily, bringing the total protein intake to 83 Gm. for the women receiving the meat supplement.

One month after delivery the meat group had an average hemoglobin value 20 per cent higher than when the meat supplementation was begun, as compared with 7 per cent and 4 per cent for the B complex and control groups respectively. The red cell values were 20 per cent higher for the meat group and 10 per cent and 12 per cent higher for the B complex and control groups. The values at the end of three months after delivery were very similar to those at the end of one month.



Comparison of hemoglobin and red cell content of the blood of women receiving meat, B complex, and no supplement during the last four months of pregnancy and for three months following delivery (in terms of the percentage of the initial value).

All of the pregnancies and deliveries were without complications. None of the subjects receiving extra meat experienced edema, whereas 3 of the B complex group and 3 of the controls had slight edema.

The nursing record showed that in six of the eleven sets of women the mother who was eating extra meat was the only one of the trio who was still nursing her infant at the end of three months. Eight of the 11 women who had extra meat nursed their babies for at least two months, 5 of the B complex group and 4 of the controls.

No effort was made to evaluate subjective evidence of any advantages of either supplement. The subjects receiving extra meat who had had previous pregnancies almost invariably volunteered the comment that they "did not feel so tired all the time" as they had during other pregnancies.

SUMMARY AND CONCLUSIONS

Because of the widespread inadequacy of the protein intake of pregnant women it is desirable to find some simple dietary recommendation which if followed would be effective in increasing their protein intake.

The study reported has tested the effectiveness of the recommendation "Eat plenty of meat—a generous serving at least twice a day." Though such a recommendation is definitely uncommon, it has the advantage of being easy to follow as well as furnishing an appreciable amount of several nutrients.

Women whose intake of protein was augmented by receiving a 5 ounce serving of meat daily in addition to their self-chosen diets during the period from four months before delivery until three months after delivery had higher hemoglobin and red cell values, less edema and better success in lactation than women who received a supplement of B complex or women who received no supplement.

The results indicate that the recommendation to normal pregnant women to increase their protein intake by eating a generous serving of meat daily in addition to their self-chosen diets would be effective in increasing hemoglobin and red cell concentration, avoiding edema and promoting lactation.

REEXAMINATION OF VETERANS DISCHARGED BECAUSE OF HEART DISEASE OR HYPERTENSION

CAPTAIN SAUL L. SILVER
and
LIEUTENANT COLONEL LYLE A. BAKER
Medical Corps, Army of the United States

During recent months we have had occasion to reexamine a large number of World War II veterans who had been discharged from the armed services because of diagnoses referable to the cardiovascular system. As this work continued, certain questions presented themselves which prompted us to analyze a consecutive series of such cases. The results of this analysis are recorded as follows:

SOURCE OF MATERIAL

The material used in this study was procured from the medical records and examinations of 500 veterans of World War II who were discharged from service because of disability due to heart disease or hypertension. In every case studied the induction examination report was available. In those cases discharged by the Army the complete hospital charts and other pertinent medical records were available. In the cases discharged from the Navy, either photostatic copies of the medical records or a medical summary was in the case file. All of this information was carefully reviewed by us and found to be extremely valuable in the study.

In addition, each veteran was examined by one or both of us. A careful history was taken, complete physical examination was done and, routinely, chest x-ray, electrocardiogram, blood Wassermann and urinalysis were obtained. Other laboratory work was done when indicated.

Nearly all of these persons came to us for examination as a result of their having applied to the Veterans Administration for compensation because of disability alleged to have been incurred in military service. With few exceptions, these cases were studied in our outpatient department.

GENERAL INFORMATION

The material studied consisted of 500 individuals, physically disqualified for duty because of heart disease or hypertension. Under heart disease we have included neurocirculatory asthenia and other disturbances of a functional character, as well as organic disease.

Only a few of these veterans were sufficiently ill to be hospitalized at the time of examination. For the most part they were in a reasonably good state of health with either mild or no subjective symptoms. There was only one woman among the 500. Fifty-two Negroes were in the group. Nearly all of these veterans had entered service from homes in northern Illinois, most of them from the vicinity of Chicago. The majority had been reared in the same area.

The average age of the entire group at the time of our examination was 29.1 years. The youngest age recorded was 19, and the oldest veteran was 53 years of age. The great majority were in the third decade. In table 1 the average age of the various etiologic groups is recorded.

The average time spent in service, from date of induction to date of discharge for disability, was 12.4 months for the entire group. It is evident (table 1) that there was no great difference in the average time spent in service as far as etiology is concerned. The shortest service, 10.6 months, was found in cases of congenital heart disease. The group with arterial hypertension had the longest period of service, 14.1 months.

The grouping of these cases in table 1, with reference to the type of disease present, is based on the diagnosis made at our examination. In some cases this diagnosis differed with that made at the time of discharge. Since neither the Army nor the Navy consistently followed the nomenclature of the American Heart Association, as we did, some academic revisions in diagnosis were necessary. Those cases in which our opinion differed with the certificate of disability discharge diagnosis will be discussed in detail later.

As would be anticipated in persons of this age group, rheumatic heart disease predominated. Of the 389 persons who had cardiovascular disease, 169 (43.4 per cent) had this type of heart disease. Arterial hypertension was the next most frequent diagnosis made, occurring in 86 (27.5 per cent) of the patients with cardiovascular disease. Other types of heart disease occurred less frequently. Coronary heart disease, however, occurred in a rather large proportion, considering the age of the group. The different etiologic groups will be discussed under their respective headings.

RHEUMATIC HEART DISEASE

There was a total of 169 persons having the rheumatic type of heart disease. The average age was 27 years and the average period of service was 12.7 months. In table 2 there is shown the incidence of the various anatomic lesions. The correlation of these lesions with the history of rheumatic fever and the time of its occurrence in relation to military service are also shown.

There were 6 patients who presented evidence other than valvular lesions on which the diagnosis was based. Five of these had abnormal electrocardiograms, 2 showing intraventricular block. One man had a history and findings indicating that he had the residuals of rheumatic pericarditis. Evidence justified the diagnosis of rheumatic carditis in these patients.

Of the 162 persons found to have valvular heart disease, the mitral valve was involved in 140 (82.6 per cent) and the aortic valve in 69 (40.8 per cent).

The criteria for the diagnosis of mitral insufficiency due to valvulitis are not very clearly defined. However, in this analysis we have adhered to the following requirements: All murmurs were of 2 plus or of greater intensity in accordance with Levine's classification. They were constantly present, tended to be harsh and varied in no significant detail on the usual maneuvers. A definite rheumatic history was required in all cases. When an aortic valvular lesion was present we required the apical murmur to be louder and more

harsh in quality than in the case of mitral valve involvement alone. We did not consider mitral insufficiency associated with mitral stenosis of sufficient clinical significance to warrant analysis.

There were 60 instances of organic mitral insufficiency without associated stenosis. In 15 of these there was associated disease of the aortic valve. In 45 (31.50 per cent) veterans there was isolated mitral insufficiency. This is approximately the same incidence as that found in selectees disqualified because of heart disease.[1] Schlesinger[2] reported a similar incidence in a follow-up on children who had suffered from rheumatic fever. All of these veterans on examination were in good health, showing no evidence of active rheumatic fever or of cardiac symptoms. The routine x-ray study of the chest revealed evidence of cardiac enlargement in 18 (30 per cent) of the 45 cases. The electrocardiogram was abnormal in 17 (28.3 per cent) cases. In 3 there was arrhythmia, 3 showed conduction defects and in 11 there was a suggestive degree of axis deviation.

TABLE 1.—*Etiologic Classification of 500 Cases*

Correlation of Average Age and Time in Service, with Etiology

	Type of Heart Disease							Hyper-tension Arterial	No Cardio-vascular Disease	Total
	Rheumatic	Hyper-tensive	Coronary	Congen-ital	Miscel-laneous	Unde-termined	Functional			
Number of cases	169 33.8%	21 4.2%	33 6.6%	7 1.4%	3 0.06%	46 9.2%	24 4.8%	86 17.2%	111 22.2%	500 100%
Average age, years	27	33	40.7	25	40	29.1	27.5	30.6	27.7	29.1
Average number of months in service	12.7	13.0	13.3	10.6	12.5	11.9	12.4	14.1	10.9	12.4

Mitral stenosis was present in 80 of the 169 veterans who had rheumatic heart disease, an incidence of 47.3 per cent. In 48 (29.6 per cent) the mitral valve alone was involved, while in 32 (19.7 per cent) mitral stenosis was associated with aortic valve disease. Among those patients in whom only the mitral valve was involved, the x-ray of the chest revealed an abnormal cardiac shadow in 18. The electrocardiogram was abnormal in 23 of the patients. Auricular fibrillation was present in 1, conduction defects in 7, right axis deviation in 9 and nonspecific abnormalities in 6.

The aortic valve was involved alone in 22 (13 per cent) of the cases. Aortic insufficiency was present in all, while in 1 case there was also stenosis of the valve. The electrocardiogram was abnormal in 8 of these 22 cases. There was abnormal left axis deviation in 4, conduction defects in 2 and nonspecific abnormalities in 2. The chest x-ray showed cardiac enlargement in 5 of the 22 cases.

Combined involvement of the aortic and mitral valves was present in 47 (27.8 per cent) of the cases. Aortic valve disease was combined with mitral stenosis 32 times and with mitral insufficiency 15 times. Aortic insufficiency was present in all, while aortic stenosis was present in 6 of those with mitral stenosis and in 1 with mitral insufficiency. Cardiac enlargement was present on x-ray examination in 28 of the 47 cases. The electrocardiograms were abnormal in 15 cases. Abnormal axis deviation was found in 10, conduction defect in 1 and nonspecific changes in 4.

The information relative to the rheumatic history of this group is of particular interest. Of the 169 cases there were 138 (80.4 per cent) in which there was a definite history of rheumatic fever. The average age at which the first attack occurred was 17 years. We were greatly aided in obtaining a history of rheumatic fever by the medical records which had been accumulated during service. In many instances the past medical history had been recorded in detail on several occasions, thereby revealing evidence of past rheumatic fever which would have been otherwise undisclosed.

The significance of the time of occurrence of the rheumatic fever as related to the period of military service is obviously important. Table 2 shows those who gave a history of rheumatic fever before entering service, those who had the initial attack while in service and those who gave a history of rheumatic fever both before and during service. Of the 169 veterans who had rheumatic heart disease, 86 (50.3 per cent) had had rheumatic fever before entering military service. The number of attacks had varied from one to ten in these people. Physicians had informed some that they had heart disease. In 40 of these men there was a recurrence of acute rheumatic fever during service. There were 52 (30.7 per cent) veterans who denied a history of rheumatic fever prior to that which occurred in service. There were 31 (18.3 per cent) who gave no definite history of rheumatic fever at any time. All of the latter group showed evidence of either stenotic valve lesions or aortic insufficiency. We did not classify apical systolic murmurs, in the absence of a rheumatic history, as rheumatic heart disease.

TABLE 2.—*Rheumatic Heart Disease*

Type of Cardiac Lesion Correlated with Rheumatic History as Related to Period of Military Service

Basis of Diagnosis Cardiac Lesion	Number of Cases	Rheumatic History			
		Before Service	In Service	Before and In Service	Negative
Valvular					
[illegible]	45	11	20	14	0
[illegible]	48	19	9	10	10
ciency	1	1	0	0	0
[illegible]	21	8	5	1	7
lesions	47	7	12	11	14
Nonvalvular					
Rheumatic myocarditis	3	0	2	1	0
Rheumatic intraventricular block	3	0	3	0	0
Rheumatic pericarditis	1	0	1	0	0
Total	169	46	52	40	31

If attention is confined to the 138 persons who had rheumatic fever, certain important facts are evident. The initial attack of rheumatic fever occurred prior to service in 86 cases (62.3 per cent). In 40 (46.5 per cent) of these there was a recurrence during military

service. It is likewise evident that of the 92 veterans who had rheumatic fever in service 40 (43.4 per cent) had suffered attacks prior to entering service.

Evidence indicates that there is a high rate of recurrence during military service among those who have had rheumatic fever. Holbrook and van Ravenswaay[3] recently reported that in a study of rheumatic fever occurring among Air Corps troops there was a previous history of rheumatic fever in 34 per cent of the patients. Wright[4] noted a history of previous rheumatic fever in 18 of 28 soldiers suffering from the disease. These figures indicate a recurrence rate higher than that reported by Wilson and Lubschez[5] for the civilian population. Massell and Jones[6] estimate that about 2 per cent of young persons of military age have had rheumatic fever. On this basis one could predict that nearly 1 per cent of all inductees might develop a recurrence of rheumatic fever in service unless such persons were eliminated because of the rheumatic history.

It is obvious that rheumatic heart disease was the major cause for disability among the 500 veterans. It is likewise apparent that in spite of careful examination a considerable number of men were inducted into service who had rheumatic valvular disease. Bland, Jones and White[7] have shown that clinical evidence of mitral stenosis rarely develops in less than three years after the onset of rheumatic fever. Aortic stenosis probably develops even more slowly. It seems reasonable to conclude that all of these veterans who had stenotic valvular lesions on discharge had definite valvular disease on induction. Delaney and his associates[8] have commented on the discovery of chronic valvular disease among air cadets who had passed from two to twelve physical examinations. It is apparent that greater care must be taken in the examination of inductees if rheumatic valvular disease is not to be overlooked.

HYPERTENSIVE HEART DISEASE

There were 21 cases classified under the heading of hypertensive heart disease. The criteria for the diagnosis was based on x-ray evidence of cardiac enlargement with hypertension or a definite history of hypertension. There was no evidence of valvular disease or any other factor to which cardiac enlargement could be attributed. As noted in table 1, the average age of this group was 33 years, six years older than the rheumatic group. The average time spent in military service was thirteen months, almost the same amount of time spent by those with rheumatic heart disease. As a whole the group was in an excellent state of compensation. Only 1 had had symptoms of early left ventricular failure while in service. At the time of our examination none of the group showed evidence of heart failure. The only abnormal physical finding was evidence of cardiac enlargement by x-ray in all cases. The electrocardiogram was abnormal in 8 patients. Six of these showed evidence of left ventricular strain, 1 delayed auriculoventricular conduction, and 1 showed an undetermined type of intraventricular block. The blood pressure was abnormally elevated in all of these persons at the time of our examination.

The records of these patients were carefully reviewed for evidence of cardiovascular disease at the time of, or prior to, induction. A history of hypertension prior to entry into service was obtained in 12 (57.1 per cent) of the group. No blood pressure was recorded at the time of induction in 2 (1 had been taking digitalis for some time). In the remaining 10 the blood pressure was normal in 2 (under 140/85) and "borderline" (under 150/90) in 8. There were 9 veterans who gave no history of hypertension prior to service. In 5 of these no induction blood pressure was recorded. In the remaining 4 the blood pressure was borderline in 3 and normal in 1. Among the 21 veterans a blood pressure under 140/85 was recorded on induction in only 3, no blood pressure was recorded in 7, and borderline blood pressure was noted in 11 of the group. We realize that the upper level of normal blood pressure used is somewhat more restrictive than that designated by Mobilization Standards (150/90).

The certificate of disability discharge diagnosis was arterial hypertension in 16 of these cases, hypertensive heart disease in 2, aortitis in 1 (Wassermann reaction negative), hypertension with aortic insufficiency in 1 and myocardial fibrosis in 1.

CORONARY HEART DISEASE

There were 33 veterans discharged because of coronary disease. The average age of this group was 40.7 years, which is considerably higher than that of the other etiologic groups. The youngest veteran, who was 25, had typical effort angina with definite electrocardiographic changes after exercise. There were 2 patients who suffered acute myocardial infarction at the age of 30. Acute myocardial infarction occurred in 6 patients under 35 years of age. The average time spent in service was 13.3 months.

The clinical manifestations were as follows: There were 21 patients who suffered classic acute myocardial infarction in service. Of these 21 cases only 4 gave a history indicating heart disease prior to service. Two had had typical effort angina of mild degree. One veteran gave a history of acute anterior infarction in 1940; however, he had withheld this information at the time of induction. The other veteran had given a suggestive anginal history, and an induction electrocardiogram showed a definite Q_3 and inverted T_3. This, apparently, was not considered significant and the man was inducted. The remaining 17 men had no history suggesting heart disease. A review of the electrocardiograms, taken at the time of the acute episode in service, showed the location of the infarcts to be anterior in 8, posterior in 12 and unclassified in 1. At the time of our examination the electrocardiograms still showed residuals of infarction in 16, intraventricular block in 1, and in 4 the tracing had returned to normal. The x-ray examination of the chest revealed enlargement of the heart in 6 and arteriosclerotic plaques in the aorta in 1. The remaining 14 were normal.

There were 10 persons who manifested angina pectoris without evidence of infarction. On close questioning, 3 of these men admitted the existence of the symptoms prior to service. There was abnormality of the electrocardiogram in 4 cases, and the x-ray of the heart showed enlargement in 3 of these patients.

The remaining 2 veterans were diagnosed as having coronary heart disease on the basis of having abnormal electrocardiograms and being in the fifth decade of life. They stated that there were no symptoms, and all findings were otherwise normal.

As judged by this series of cases, it seems that the elimination of such persons at the time of induction is very difficult. Only 7 of the 33 gave a history indicating heart disease. The examiner is dependent on the accuracy of the history given, and more careful attento this point might have eliminated a few. Electrocardiograms would have given evidence in some of these men.

CONGENITAL CARDIOVASCULAR DISEASE

There were only 7 of these 500 veterans who had congenital cardiovascular disease. This is an incidence of only 1.4 per cent, which is much lower than that found in inductees. In the examination of inductees Levy, Stroud and White[9] found 4.4 per cent, while Wilburne and Ciccolini[10] found 12.2 per cent had congenital cardiovascular lesions. Porter[11] found an incidence of congenital heart disease of only 1.6 per cent among patients with all types of cardiovascular disease in a large army hospital, which is approximately the same as the 1.4 per cent noted in this series. A comparison of these figures would indicate that nearly all congenital heart disease is eliminated at the time of the induction examination. The fact that nearly all congenital heart lesions are associated with loud murmurs probably accounts for this fact.

The congenital lesions found among these 7 persons were as follows: Three had coarctation of the aorta, 2 had patent ductus arteriosus, 1 had a right aortic arch and 1 had severe congenital deformity of the chest leading to pulmonary hypertension and cor pulmonale. The average age was 25 years and they spent an average of 10.6 months in service. Two of the patients with coarctation of the aorta had a history of hypertension, and 1 patient with a patent ductus arteriosus knew he had a heart murmur before entering military service. The patient with congenital deformity of the chest had had a low effort tolerance all of his life, and this had become much more apparent during service. At the time of our examination he had increased venous pressure and was obviously quite disabled.

These results would indicate that few people with congenital cardiovascular disease are inducted into military service and that it is an unimportant cause of disability discharge.

HEART DISEASE OF MISCELLANEOUS ETIOLOGY

Three persons are grouped here because the small number does not justify separate classifications. Two of them were discharged because of myocarditis: 1 following diphtheria, and the other one associated with bacteremia. In both instances the electrocardiograms were abnormal and we concurred in the diagnosis of infectious myocarditis. There was 1 patient with cardiovascular syphilis. This man had symptoms of coronary insufficiency with x-ray evidence of aortic dilatation and an abnormal electrocardiogram. He gave a history of a penile lesion in 1927 with some antisyphilitic therapy. The blood Kahn reaction was positive.

HEART DISEASE OF UNDETERMINED ETIOLOGY

Among the 500 veterans studied there were 46 instances in which the heart was found to be abnormal but no definite etiologic factor could be established. The past medical history disclosed no cause, and the physical findings and laboratory work disclosed nothing of a specific character which would indicate the etiology. The average age of the group was 29.1 years. The average time spent in service for this group of veterans was 11.9 months. These cases can well be divided in accordance with the type of abnormality which served as the principal basis for a diagnosis of heart disease.

There were 21 individuals who presented systolic murmurs of such a character as to be considered abnormal. All of these murmurs were so located as to indicate that they were of mitral origin and of 3 plus or greater intensity. They were constantly present, irrespective of position, respiration or exercise, and continued through all or the greater part of systole. Some were harsh in quality, while others were soft and blowing. In most instances the murmur was the only abnormal cardiovascular finding. There was one abnormal electrocardiogram showing a prolonged PR interval, and in 4 cases the x-rays of the chest indicated slight cardiac enlargement. At no time had there been any significant cardiac symptoms in any of these veterans. Seven of the 21 had knowledge of the presence of a murmur before entering service. Two of these had been previously rejected because of this physical finding.

It seems that some authors who studied persons of a similar age group have classified such cases under rheumatic heart disease. The discharge diagnosis in all of these cases was chronic valvular heart disease. While it is reasonable to assume that rheumatic valvulitis is a common cause for such murmurs, our experience has not led us to believe that we can determine the physical condition of the mitral valve with any great assurance from the interpretation of a systolic murmur alone. A similar experience was reported by Rednick.[12] In a series of cases studied at postmortem he was unable to find any anatomic explanation for 22 per cent of the systolic murmurs heard during life. In the absence of any history of rheumatic fever or other concrete evidence of causation we have conservatively classified these murmurs as of undetermined etiology. A good many were undoubtedly rheumatic in origin, while some were possibly functional in character. It was obvious that these men had been discharged because of the abnormal auscultatory finding rather than because of physical disability.

There were 19 in whom the diagnosis of heart disease was primarily based on an abnormal electrocardiogram. In 8 there existed bundle branch block, one being of the short PR interval type. In 2 there was a prolonged PR interval of 0.25 second. In the remaining 9 there were T wave abnormalities of nonspecific type. Cardiac enlargement by x-ray was present in only 1 of these veterans. In 7 of these 19 cases there existed, prior to service, a history of symptoms or medical opinion which was strongly indicative of heart disease. It seems that coronary disease was probably present in some, while rheumatic involvement may have been present in others; however, a definite etiology could not be established.

The principal manifestation in 4 of this group was paroxysmal attacks of tachycardia. Two had episodes of auricular fibrillation, 1 had paroxysmal ventricular tachycardia and 1 had episodes of frequently recurring multifocal premature ventricular beats. The 2 patients who manifested paroxysmal auricular fibrillation had enlargement of the heart by x-ray examination. Only 1 gave a history of cardiac symptoms prior to service, having had episodes of auricular fibrillation.

Two were found to have unexplained cardiac enlargement. One had been discharged with the diagnosis of hypertensive heart disease, but there were no abnormal blood pressure recordings in the record or at our examination. The other had a certificate of disability discharge diagnosis of neurocirculatory asthenia.

FUNCTIONAL HEART DISEASE

Under the heading of functional heart disease we have grouped those cases which had some type of cardiac disturbance which was considered not organic in nature, including neurocirculatory asthenia. There were 24 veterans (4.8 per cent) of the entire series who presented such disorders. The average age of these men was 27.5 years, and the average time spent in service was 12.4 months.

There were 12 men who had cardiac arrhythmias. In 7 the arrhythmia was paroxysmal auricular tachycardia. There were 3 with paroxysmal auricular fibrillation and 2 with ventricular premature contractions. In all of these cases the diagnosis had been sustained by electrocardiograms taken during the time the arrhythmia was present. Six of these veterans gave a clear history of the occurrence of the arrhythmia prior to service. There were no other abnormal cardiovascular findings in any of these cases and there were no symptoms other than those resulting from the disturbed rhythm.

The diagnosis of neurocirculatory asthenia was made in only 12 of 500 cases, an incidence of 2.4 per cent, which is surprisingly low. However, the incidence of this condition found in inductees rejected for heart disease has been comparatively low. It was noted in 4.9 per cent of 4,994 rejectees by one group of examiners,[9] and in 1 per cent of another series of rejectees.[10] Of the 12 persons, 9 had been discharged because of neurocirculatory asthenia. The remaining 3 had been discharged with a diagnosis of organic heart disease which we did not find present. Seven of these 12 persons gave a history of similar symptoms prior to service.

ARTERIAL HYPERTENSION

There were 86 veterans who were found to have hypertension. This comprised 17.2 per cent of the 500 cases. The average age of the group was 30.6 years at the time of our examination, with an average of 14.1 months spent in military service. This is the longest average period of service of any of the groups.

Hypertension was considered to begin at a systolic pressure over 150 mm. of mercury or a diastolic pressure over 90 mm. of mercury. We classified systolic pressures between 140 and 150 and diastolic between 85 and 90 as "borderline."

As might be expected, the degree of hypertension found in these veterans was either mild or moderate. Only 1 patient had a blood pressure over 200 systolic and 110 diastolic. In the majority the systolic pressure ranged between 150 and 165 and the diastolic between 90 and 105 mm. of mercury.

While some of these men came to the attention of the medical officers because of routine physical examinations or while under treatment for an unrelated condition, a surprising number reported to sick call because of symptoms. There were 58 who consulted the doctors because of feeling ill, and hypertension was thus discovered. The most frequent symptoms complained of were headache, palpitation, fatigue and nervousness; less frequently precordial distress was a complaint. These subjective complaints were more generally present in this group of veterans than is usually noted in civilians with a similar degree of hypertension. It hardly seems probable that the hypertension was the direct cause of the symptoms but more likely that the psychologic makeup of these persons rendered them less adaptable to military service. Psychic conflicts, and anxiety resulting therefrom, might well cause such symptoms.

The discharge diagnosis was arterial hypertension in all but 5 of these persons. One had been discharged for rheumatic myocarditis and 1 for valvular heart disease. The diagnosis in both cases was presumably based on an apical systolic murmur, since there was no history of rheumatic fever in either case. There were 3 who were given a certificate of disability discharge on neurocirculatory asthenia.

With reference to evidence of hypertension prior to service, there were 36 (41.8 per cent) who gave a history of hypertension. In 14 of these no blood pressure was recorded on the induction examination. The blood pressure was "borderline" in 16 and below 140/85 in 6. Among the 50 men who had no history of hypertension the blood pressure was not recorded on induction in 23, it was "borderline" in 11 and it was under 140/85 in 16.

The high incidence of a previous history of hypertension in Navy men who were found to have high blood pressure has been commented on by Master.[13] Traum and Wilcox [14] found that 44 per cent of a small number of men discharged for hypertension gave a previous history of this condition. This corresponds well to the 41.8 per cent noted in this series. It is apparent that the past history of hypertension and the induction blood pressure deserve serious attention when judged by these persons discharged for hypertension.

CHANGES IN DIAGNOSIS RESULTING FROM REEXAMINATION

Reexamination of these 500 veterans led us to differ, in a considerable number, with the diagnosis on which disability discharge had been based. In table 3 we have indicated how the cases under the various certificate of disability discharge diagnoses were reclassified at the time of reexamination. It is apparent that in some veterans having heart disease there was a difference of opinion as to the type of disease present. Such disagreement is largely academic from the point of view of fitness for military service and is of little concern.

The most important difference of opinion was in a group of 111 cases in which we were unable to confirm the diagnosis of cardiovascular disease. For discussion, these cases can be grouped in accordance with the certificate of disability discharge diagnosis so that certain facts may be better emphasized.

The most common unconfirmed certificate of disability discharge diagnosis was that of valvular heart disease. Forty of the 111 veterans were discharged with this diagnosis. Twenty-six of these had suffered from acute rheumatic fever in service and were discharged shortly thereafter. On reexamination we found that 23 of these men had faint (1 plus) apical systolic murmurs and 3 had no abnormal findings. In 14 of these 40 veterans there was no history of any etiologic factor. Systolic murmurs were present in all. In 3 men they were of 2 plus intensity, and in 11 the murmur was of less than 2 plus intensity. X-ray and electrocardiographic studies were normal in all of the 40 cases. All were in good health and had no cardiac symptoms.

---

[13] Master, A. M.: *Hypertension in the Navy*, Bull. New York Acad Med. **19**: 704-712 (Oct.) 1943.

[14] Traum, A. H., and Wilcox, B. B.: *An Analysis of 150 Cases of Cardiovascular Disease in World War II Veterans*, Mil. Surgeon **95**: 5 10 (July) 1944.

At the time of our examination we did not believe that there was sufficient evidence to sustain a definite diagnosis of heart disease. Those with a rheumatic history were considered as "possible" rheumatic heart disease, and the diagnosis was recorded as "systolic murmur with history of rheumatic fever." The murmurs noted in the 14 without a history of rheumatic fever were classified as physiologic and not indicative of heart disease.

It seems that several factors may have played a part in this change of diagnosis. The use of the diagnosis of "valvular heart disease," while it implies anatomic changes, does not place the examiner under such strict responsibility for determining the etiology or character of these changes as does the nomenclature of the American Heart Association. Since we followed that nomenclature, it is probable that some inconsistency resulted because of the difference in terminology used.

There was also evidence that the character of the systolic murmur had actually changed, in the interval since discharge, in some of the persons who had had acute rheumatic fever during service. A comparison of the description of the murmurs at the time of discharge with our findings indicated that the murmurs had decreased in intensity or had even disappeared in some cases. How often this occurred we cannot be certain, since the relative intensity of the murmurs had not been described in all patients. It is a well recognized fact that relatively loud systolic murmurs occurring during the course of rheumatic fever may later show appreciable regression or disappear.[15] Since, on the average, reexamination took place nearly a year after discharge, this was probably not an uncommon cause for change in diagnosis.

Furthermore, Holbrook and van Ravenswaay[3] recently indicated that there has been a considerable change in the policy of the Air Corps toward rheumatic fever and slight or questionable evidence of rheumatic heart disease. They report that separation from service has dropped from 85 per cent to 25 per cent. It is probable that a similar change of policy was reflected throughout the armed forces. Since these men were discharged during the early months of the war, when the attitude toward rheumatic fever or any suggestion of rheumatic heart disease was quite intolerant, it is likely that diagnosis and disposition were considerably influenced by this prevailing attitude.

Reports in the literature concerning the follow-up of similar cases indicate that a comparatively small percentage of these persons will eventually develop definite rheumatic valvular disease. Boone and Levine,[16] in a ten year follow-up, found that only 4.8 per cent developed valvular heart disease, while Ash,[17] in a similar study of children, reported that only 18 per cent developed valvular disease. These findings justify the conservative diagnosis made in this group of cases at this time. Interval examinations in the future will be necessary to determine the outcome in each case.

There were 8 veterans who suffered acute rheumatic fever in service, during which time they developed definitely abnormal electrocardiograms. They were discharged because of rheumatic carditis. At reexamination the electrocardiograms were all normal. Four had 1 plus apical systolic murmurs. All 8 cases were classified as "possible" rheumatic heart disease. Improvement in the clinical findings was clearly the reason for lack of conformity with the certificate of disability discharge diagnosis.

Neurocirculatory asthenia was the second most frequently unsustained discharge diagnosis. Forty-two of the 500 veterans were separated from service on the basis of this disability. At the time of reexamination the diagnosis was sustained in 9 of these men, 4 others were found to have organic cardiovascular disease, and 1 was classified as having paroxysmal auricular tachycardia. In the remaining 28 veterans we were unable to sustain the diagnosis of cardiovascular disease. Two factors would seem to be responsible for this disagreement in diagnosis.

A difference in diagnostic criteria was the cause in some cases. Though much has been written concerning this entity, the criteria for diagnosis are still rather

indefinite. There are those who will establish the diagnosis almost entirely on subjective complaints; others require definite objective evidence of neurocirculatory instability such as erratic heart rate, unstable blood pressure, sweating, unusual flushing or pallor, and tremor. We agree with the latter criteria for diagnosis. Those people who had only subjective complaints were thought to be undistinguishable from the "neurosis" and so were referred to the psychiatrist for diagnosis. This difference in point of view was responsible for failure to sustain a diagnosis of neurocirculatory asthenia in a few cases.

The more important factor responsible for our failure to concur in the diagnosis was a change in the symptoms and physical findings of the veteran from those described at the time of discharge. It is generally agreed that an inherent predisposition plus environmental factors are necessary to precipitate the neurocirculatory asthenia syndrome. Military service during time of war furnishes the most ideal environment. However, if such an individual is discharged and returns to a familiar civilian environment, free from anxiety and military responsibility, it is reasonable to presume that symptoms and signs may recede so that the syndrome becomes clinically latent. This apparently occurred in most of these 28 veterans. At the time of reexamination there was not sufficient evidence on which a diagnosis could be based.

As judged by this series of cases it would appear that neurocirculatory asthenia is a much less frequent cause for separation from service in this war than it was during World War I. McCrudden and White[18] reported an incidence of 45 per cent, and Lewis[19] noted an even higher incidence during the war. These figures are extremely high when compared with the separation incidence of 8.4 per cent in this series. It seems likely, however, that many such cases are being classified under neuropsychiatric diagnoses, such as "battle fatigue," "anxiety states" or neurasthenia, during the present war. We are in agreement with a policy of diverting the diagnostic terminology away from the cardiovascular system.

There were 26 veterans who were discharged because of arterial hypertension whose blood pressure was under 150/90 mm. of mercury at the time of our examination. Seven of these gave a history of abnormal blood pressure before entering service. A review of the induction examinations showed the blood pressure recorded under 140/85 in 9, "borderline," under 150/90, in 7, and no blood pressure recorded in 10. As would be expected, the blood pressure readings recorded during service revealed only mild elevation. A diastolic pressure of 100 or over was recorded in only 10 cases. The highest systolic pressure recorded was 176 and the highest diastolic pressure was 112. Many cases showed wide fluctuations in pressure from normal to abnormal. Only 13 of the group had symptoms at the time of discharge. These symptoms were headache, nervousness, palpitation and breathlessness. One patient had been troubled by epistaxis. All were in good health at the time of reexamination and only a few had mild symptoms, as already recorded.

Blood pressure has been found to present a very difficult problem in determining physical fitness for military service. The difficulty is largely due to the frequency of the so-called "nervous hypertension" among young persons and the inadequate means of differentiating it from true essential hypertension. While essential hypertension usually begins with a period of fluctuating blood pressure, the incidence of the development of true hypertension during the next few years in people of this age group is probably very small. Levy and his associates[20] found an occurrence rate of 2.5 per thousand persons years under observation for army officers of approximately this same average age who had manifested transient hypertension. This figure gives support to those who believe that the attitude toward induction blood pressure should be rather liberal. However, this same liberal view will need to be adopted by both Army and Navy if frequent discharges for transient arterial hypertension are to be avoided.

A study of the records and the course of the blood pressure in these cases would indicate that for the most part they may be classed as "nervous hypertension." It is likely that military environment caused sufficient psychic stress to give rise to transient elevation in blood pressure. The symptoms complained of were strikingly similar to neurocirculatory asthenia. The similarity extended further in that return to civilian life relieved that psychic stress to such an extent that the blood pressure returned to normal.

Three patients discharged because of cardiac arrhythmia were placed in this group. Neither the medical records nor our findings revealed sufficient evidence of disturbed rhythm to classify the cases as abnormal.

There were 6 patients who were discharged because of organic disease in whom our examination revealed nothing abnormal. A review of the medical records did not reveal, in our opinion, sufficient basis for the diagnosis made at time of discharge. In only these 6 cases was there entire disagreement with the clinical findings and the certificate of disability discharge diagnosis.

Even though the certificate of disability discharge diagnosis of cardiovascular disease was unconfirmed in 111 of the 500 cases, it is important to note that an improvement in the condition of the patients made a change of diagnosis necessary in many cases. In the remainder of the cases there was little disagreement with clinical findings recorded at the time of discharge. Changes in diagnosis in these cases resulted from a difference in criteria used in clinical classification. In only a few cases was there complete clinical disagreement.

SUMMARY

A careful analysis of the records of 500 veterans discharged because of heart disease or hypertension has been made. Obviously the necessity of discharging persons from military service because of disability a year after induction involves a great loss of both time and money with regard to military training. In addition, the federal government is obligated to a future responsibility which is of no small concern. Any information which might prevent such incidents is therefore of great value.

Rheumatic heart disease was by far the most common type of cardiovascular disease noted among these veterans. A definite history of rheumatic fever prior to entrance into military service was present in 50.3 per cent of these cases. In 52 cases definite stenotic valve lesions were discovered two years or less following induction. Among those giving a negative history for rheumatic fever we know the valvular disease was not acquired during service, and therefore it must be concluded that it existed prior to induction. The tendency for rheumatic fever to recur during military service is also confirmed.

[19] Lewis, Thomas: The Soldier's Heart and the Effort Syndrome, ed. 2, London, Shaw & Sons, 1940.

[20] Levy, R. L.; Hillman, C. C.; Stroud, W. D., and White, P. D.: Transient Hypertension, J. A. M. A. **126:** 829-833 (Nov. 25) 1944.

Arterial hypertension was the second most common cause of cardiovascular disease. Twenty-one of these persons were found to have hypertensive heart disease, and in 86 the hypertension was uncomplicated. There was a history of hypertension prior to induction in 44.8 per cent of all cases. It was recorded above 140/85 "borderline" in 35.5 per cent and under 140/85 in 23.3 per cent.

Coronary heart disease was relatively frequent considering the average age of the veterans. Approximately 4 per cent of all discharges were due to acute myocardial infarction.

Congenital and syphilitic cardiovascular diseases were rarely noted and were unimportant as a cause of disability discharge.

Difference of opinion regarding the significance of systolic murmurs proved to be the most common cause for a change in diagnosis. Some inconsistency was noted in that murmurs of a type usually considered acceptable for induction sometimes served as a basis for certificate of disability discharge disposition. This supports the policy of the Philadelphia board,[21] which was rejecting inductees with systolic murmurs not thought to be organic, considering the possibility of subsequent discharge on the basis of these murmurs.

In this series of cases neurocirculatory asthenia was a much less frequent cause for discharge than it was during World War I. This may be due to the fact that these patients are being classified under neuropsychiatric diagnoses.

There was a definite tendency for the signs of neurocirculatory asthenia and hypertension to disappear following return to civilian environment. This indicates that poor psychologic adjustment to military life was responsible for transient clinical manifestations.

The certificate of disability discharge diagnosis of cardiovascular disease was unconfirmed in 111 of the 500 cases. This was due, in the majority of instances, either to a change in the physical condition of the veteran or to a difference in the criteria and terminology used in classification.

A review of the medical records of these veterans disclosed that in approximately 40 per cent there was a history of an etiologic factor, symptoms referable to the heart or of abnormal physical findings which antedated their entry into service. More time devoted to the careful questioning of inductees with regard to these factors might have suggested the presence of cardiovascular disease. The routine referral of persons who had suggestive histories to physicians especially trained in cardiovascular diseases would have undoubtedly uncovered evidence of disease in many. We realize that some persons will withhold such facts, while others may fabricate information. However, it seems the additional time and expense required would have been insignificant compared to the time that has been lost and the expense the public will bear during the coming years.

ISOSPORA HOMINIS INFECTION IN MAN

COMMANDER ARTHUR A. HUMPHREY (MC), U.S.N.R.

Isospora hominis infection in man, sometimes termed human coccidiosis, is a rare and poorly understood disease, the pathogenicity of the organism even being open to some question. Despite the recognition of some 240 cases, the bulk of them occurring in World War I in the Mediterranean area, it has been possible to study very few from the clinical standpoint. Magath[1] in 1935, three years after he observed the first case in the United States, reviewed the literature thoroughly and photomicrographs reprinted from this paper in a readily available textbook[2] form an excellent basis for the recognition of the parasite.

The oocysts which are found in the stools are probably ingested as such in food and drink, and since closely allied coccidia are found in many animals these creatures doubtless serve as a reservoir. The ovoid, glassy cysts measure 18 to 33 microns in length and 12 to 16 in breadth. The capsule may be doubly refractile, although in certain of the organisms it appears as a single layered translucent shell, which may become distorted or wrinkled on standing or in fixed slide preparations. The poles of the ovoid may be smoothly rounded, or one may be bluntly rounded. In some instances the shell appears as if it had been bilaterally pinched near the polar ends. The rounded mass of granular protoplasm in the center is usually single when the stool is fresh and tends to fill the beam of the boatlike capsule, although if ovoid it has a long axis parallel with that of the cyst. Shortly after passage this divides into two sporoblasts, although this may readily occur even by the time the specimen is examined. On further standing the sporoblasts will increase to four or eight and the granular appearance will be replaced by vermiform, rodlike structures.

While there are no accurate data to substantiate it, the oocyst is described as invading the epithelial cells covering the mucosa of the small bowel. A small bottle-shaped abscess follows this penetration, and schizogony and sporogony are suspected of taking place with the formation of new oocysts, which are poured into the lumen of the bowel. These apparently lack invasive power, as the disease is briefly self limited, all symptoms ceasing spontaneously within a few days to a few weeks.

Many of the reported cases have been asymptomatic or have been associated with some concomitant disorder, such as ulcerative colitis,[3] and the symptoms could not be properly evaluated. Laboratory infection of an accidental nature has occurred in 1 reported instance,[4] which was followed by a mild diarrhea after an interval of six days and continued for five weeks until halted by treatment. While this case was more protracted than the usual one, which lasts only a few

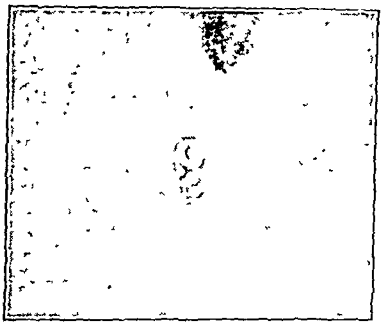
days to a week or two, it has assisted in estimating the incubation period. Other symptoms that have been reported are abdominal discomfort, flatulence, weight loss and lassitude.

The stools are usually described as being light in color, fatty and with an excess of undigested material. The isospora may be easily overlooked; because of their cellophane-like translucency they have been reported as remaining in the stool for only a few days, while other authors have continued to observe them for a month or more. A blood eosinophilia as high as 38 per cent has been recorded.[5]

These case reports are presented as it is felt that they add clinical support to the probable pathogenicity of the isospora when found in some individuals.

REPORT OF CASES

Case 1.—A soldier aged 28 entered the hospital on July 1, 1945 complaining of discomfort in the right upper quadrant and intolerance to certain foods. These symptoms had been intermittently present since the fall of 1944, when he had severe pain in this area and a stone was removed and a cholecystectomy performed. The next serious attack occurred on June 22, 1945 while he was on Okinawa. The patient had no diarrhea but had suffered from constipation. He was afebrile, and further physical examination was essentially negative except for tenderness in the old operative site.



Appearance of Isospora hominis in case 2, illustrating division into two sporoblasts.

On entry the leukocytes numbered 8,500, of which 7 per cent (600 per cubic millimeter) were eosinophils. The gallbladder did not visualize with the dye, and the other x-ray studies of the gastrointestinal tract were negative. A gastric analysis was within normal limits. On July 10 the leukocytes numbered 14,800, with 6 per cent eosinophils (888 per cubic millimeter). Abdominal discomfort was still present. Stools examined on this date and on July 15 were normal but on July 16 Isospora hominis was found in small numbers in two successive stools. The patient at this time had just completed a course of tetrachlorethylene and caprokol directed against his unexplained eosinophilia. It was felt that some of the symptoms were due to postoperative adhesions. A few parasites were still present at the time of his evacuation on July 31, and further follow-up was not possible.

Case 2.—A marine aged 31 entered the hospital on July 21, 1945, following his evacuation from Okinawa, with the diagnosis of acute myositis. A month before he had been forced to leap from a cliff to escape fire and injured his back, he was unable to move because of pain for some time and he also developed a urinary retention for five days. There were no x-ray findings. Improvement had been steady but slow, the pain in the lumbosacral area being persistent. He had arrived on Guam from the United States in the first week in April 1945 and was sent to Okinawa on the last of the month. The bulk of the men in his unit suffered from a brief diarrhea during the last week in May, but, while the others were affected for only a day or two, in his case the stools were frequent and watery for three weeks. In the first few days of the illness he vomited and had a mild fever (101 F.) with excessive perspiration. He did not observe any blood in the stools. He was confined to a field hospital part of this time, and some improvement followed the use of paregoric and a bismuth preparation. Army units obtained rectal cultures from his unit at the time of the outbreak without apparent result. A week or two prior to this episode they had killed and cooked a native goat, and although they ate some captured rations in addition to their own, all were tinned. The water supply came in part from a native spring, but halazone tablets had been added in such numbers that it was unpalatable. Following his arrival at this hospital he complained of a dull, gnawing pain in his abdomen, constipation and an unusual amount of flatus.

Physical examination was essentially negative except for evidence of weight loss and tenderness and spasm over the sacrolumbar area. He was afebrile during his hospital stay.

A leukocyte count of 7,900 on July 31 revealed 15 per cent eosinophils, the remainder of the differential count being essentially normal. A stool specimen examined on August 2 contained a number of Isospora hominis organisms and the stools continued to be heavily laden with them until his discharge to duty on August 7.

Case 3.—A Marine aged 19 entered the hospital on July 3, 1945 with the diagnosis of paroxysmal tachycardia. In the past eight months he had experienced six typical attacks with characteristic symptoms and findings. In the interval he had had no complaint.

During his thirty-one months of overseas duty he had been in Samoa, the Hawaiian, Solomon and Marshall groups and lastly in Okinawa, from which he returned to Guam on July 13. One week after he arrived, on July 20, there was a sudden onset of a watery diarrhea and he felt feverish, although he did not turn into the sick bay. After three days of diarrhea it abated for a day following paregoric and then returned for two days. He did not observe any blood in the watery stools and felt only a mild malaise. Since that time he had had no gastrointestinal symptoms. No other man in his unit was affected at the time.

Physical examination was negative. The urine contained 5 leukocytes per high power field. X-ray examination of the heart and chest was negative. An electrocardiographic tracing demonstrated a sinus tachycardia with no permanent changes. On August 4 he had a hemoglobin of 85 per cent and a leukocyte count of 10,900. The differential count was segmented cells 54 per cent, lymphocytes 19 per cent, monocytes 15 per cent, and eosinophils 12 per cent (1,308 per cubic millimeter). On August 8 Isospora was found in numbers and this was repeated on the 9th. On August 11 a careful search failed to reveal any parasites. On August 15, the last day on which it was possible to follow the patient, a few parasites were still present.

COMMENT

If the salient symptoms of Isospora infection are diarrhea and abdominal pain or discomfort, 2 of the 3 cases show the former and all the latter symptoms. In the first case, however, the occurrence of abdominal discomfort as a manifestation of this infection must be viewed with caution, since his difficulty may be due to some residual affair following his cholecystectomy of the previous year. The fact remains, however, that his only recent severe episode occurred shortly after his arrival on Okinawa. Diarrhea is also a common symptom in the Western Pacific area, but it ordinarily affects a number of men in the same unit simultaneously. The third patient was the only one affected, and in case 2 the diarrhea continued for three weeks and was in no way similar to the transient illness affecting the others of his command. It is conceivable that, if the degree of severity is due to a quantitative effect, he merely might have ingested more oocysts than the others.

The diarrhea in the 2 cases so affected was described as watery, and blood was not present. One lasted five days and the other three weeks. The stools when examined in this hospital were normal except for the presence of Isospora, which was found in all of the cases repeatedly, and apparently for the first time. In 1 case they appeared intermittently. The longest period in which they were continuously found was fifteen days, at the end of which time the patient was discharged.

Taking a commonly accepted figure of 400 eosinophils per cubic millimeter as a significant level, all of the cases showed an eosinophilia without other cause. In the 3 this varied from 7 per cent, with an absolute count of 600 cells, to 15 per cent, or 1,300 cells per cubic millimeter. It must be pointed out, however, that idiopathic eosinophilia, or so-called tropical eosinophilia, is common in the lower lattitudes and could have been present prior to the invasion of the parasites.

---

[5] Manson-Bahr, P.: The Dysenteric Disorders, Baltimore, Williams and Wilkins Company, 1943, pp. 267-268.

One patient, and perhaps another, had a fever early in the course of the disease. Two complained of a previously described symptom, flatulence. Leukocytosis was present in but 1 case and that was not present on arrival; it is considered that they were seen too late in the disease for any conclusion on this score.

It is of interest that the 3 patients had been on southern Okinawa within the same period of a few weeks, and, while they did not belong to the same unit, troop movements might have carried them in the same areas. Water was described as being well chlorinated, but it is questionable what degree of chlorination is required to destroy this parasite. Native vegetables might also have been a source of infection, as warnings as to their potential danger often went unheeded.

The Isospora parasites isolated from these patients failed to take any staining procedure, although following fixation by Schaudinn's fluid they were well delineated as light, glassy, ovoids against a dark hematoxylin stained background. Such preparations deteriorated in a few weeks. Dichromate or formaldehyde suspensions of the stool will keep for some time.

SUMMARY

Three cases of Isospora hominis infection in man have been studied in which no other intestinal parasite, or infection, was present to cloud the clinical picture. Abdominal discomfort was the symptom common to all, while a self-limited diarrhea occurred in 2 of the 3 cases.

The infection is apparently associated with a moderate, but definite, eosinophilia, which in the absence of other causative factors may support the contention that Isospora is pathogenic.

From the peregrinations of these patients, certain facts have been brought out in regard to the incubation period; it may be longer than previously suspected, or ten to twenty days. Oocysts were observed for as long a period as fifteen days during hospitalization and nine weeks after the onset of the illness.

Concussion of the Spinal Cord.—Grossly, in a few instances the spinal cord immediately, or a few days after the blow, may be swollen at the level of the injury and possibly at one or two segments below or above the main lesion. The dura and pia-arachnoid are usually intact unless the dura is pierced, in which case they may show slight tears, be edematous and distended and contain slightly blood-tinged fluid. On sectioning, the cord may appear normal or show edema and small scattered hemorrhages. Thrombi and stasis in the blood vessels have been described. In severe cases of spinal concussion the outlines of the gray matter may disappear, and the cut surface has a pulp-like softened appearance. These pulp-like, necrotic areas, as in this instance, may occur at other regions than the impacted area. Cylindrical cavities of one to two millimeters in diameter or even larger may be noted. These occur mostly in the dorsal horns or in the posterior columns near the gray matter. These cavities may extend longitudinally upward and downward for two or three segments. They may be visible to the naked eye and are filled with grayish or brownish gelatinous material and may contain blood serum, histiocytes, compound granular corpuscles and less frequently red blood cells.—Davison, Charles: Pathology of the Spinal Cord as a Result of Trauma, in Trauma of the Central Nervous System, Baltimore, Williams & Wilkins Company, 1945.

Clinical Notes, Suggestions and New Instruments

BRAIN ABSCESS ASSOCIATED WITH CONGENITAL HEART DISEASE

Report of a Case with Complete Recovery

EDMUND A. SMOLIK, M.D.
RUSSELL J. BLATTNER, M.D.
and
FLORENCE M. HEYS, Ph.D.
St. Louis

The association of brain abscess with congenital heart disease has not been emphasized sufficiently in the medical literature. Robbins[1] in a recent comprehensive report collected from the literature 23 cases of brain abscess associated with congenital heart disease and added 3 cases of his own. These 3 cases of brain abscess, all associated with the tetralogy of Fallot, were found when Robbins reviewed 58 cases of congenital heart disease in a series of 7,880 consecutive autopsies. Of the 26 cases described, it is noteworthy that in only 3 instances was the diagnosis of brain abscess established ante mortem and surgical intervention attempted.[2]

The present case is reported to call attention to the association of brain abscess with congenital heart disease and to point out that surgical intervention along with supportive medical care may effect a complete cure in some cases.

REPORT OF CASE

J. H., a white girl aged 9 years, was admitted to St. Louis Children's Hospital on Aug. 21, 1944 with the chief complaints of headache, vomiting and loss of weight for four weeks. Approximately six weeks before admission the patient had suffered a chill while attending the theater. At that time she felt feverish but was not especially ill. After twenty-four hours she seemed completely recovered. There were no adverse symptoms until two weeks later, when she began to have recurrent headache accompanied by vomiting. These headaches were severe and localized for the most part in the frontal area just above the left eye. The attacks of headache lasted for about five hours and were associated with severe intractable vomiting. She complained of weakness and went to bed of her own volition. The intermittent headaches and attacks of vomiting continued, and the child lost weight steadily. There were no further chills, but the parents noted low grade fever and gradual loss of strength.

She was admitted to another hospital for observation. The important findings there were as follows: X-ray examination of the skull revealed increased intracranial pressure. Examination of the eyegrounds showed congestion of veins but no definite papilledema. There was questionable lid lag on the left. An electrocardiogram taken at that time was interpreted as revealing sinus arrhythmia, normal conduction time, variable T waves and rotation of the electrical axis about 180 degrees from normal. X-rays of the sinuses were normal, and x-ray of the chest showed the lung fields clear. The mediastinum, heart and great vessels were thought to be within normal limits. The white blood cell count was 14,500. Blood culture was sterile. While in the hospital, the patient continued to vomit and required parenteral feeding. At this time the total weight loss since the onset of illness was estimated at 10½ pounds (4.7 Kg.), approximately one fifth of the body weight. She was transferred to St. Louis Children's Hospital for further study.

The family history was noncontributory, except that two years previously the father had had an amebic abscess of the liver, which was treated successfully. The past history was

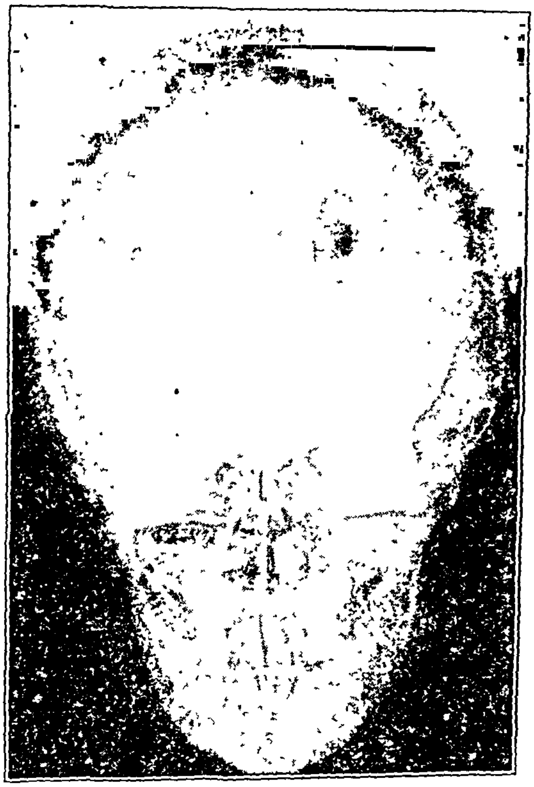
Dr. Smolik is now a member of the Department of Surgery, Section of Neurosurgery, St. Louis University School of Medicine.

[1] Robbins, S. L.: Brain Abscess Associated with Congenital Heart Disease, Arch. Int. Med. **75**: 279 (May) 1945.

[2] Ingham, D. W.: Paradoxical Embolism, Am. J. M. Sc. **196**: 201 (Aug.) 1938. Wechsler, I. S., and Kaplan, Abraham: Cerebral Abscess (Paradoxic) Accompanying Congenital Heart Disease, Arch. Int. Med. **66**: 1282 (Dec.) 1940.

significant in that a diagnosis of congenital heart disease had been made at 2 months of age. The physician called attention to a loud murmur heard over the precardium. According to the parents, however, the patient had never suffered from "heart trouble" and was never cyanotic. She had had the usual childhood diseases: pertussis at 5, measles at 7, chickenpox at 8. An appendectomy had been performed at 5 years.

On admission to St. Louis Children's Hospital, the patient was alert and cooperative. She complained of headache in the frontal area. She was extremely malnourished. There was no cyanosis and no clubbing of the fingers or toes. The significant findings were as follows: No definite enlargement of the heart was noted; a loud systolic murmur was audible over the precardium, with maximal intensity to the left of the sternum in the second intercostal space. There was no palpable thrill. Fluoroscopy showed widening of the superior mediastinum, with considerable pulmonic bulge. X-ray examination of the chest for heart size revealed the cardiac silhouette within normal limits, although there was some prominence in the region of the pulmonary artery. The hilus shadows and lung markings were not unusual. The ears, nose and throat, lungs and abdomen were within normal limits. Neurologic findings included an equivocal Macewen's sign, questionable left sixth nerve weakness and suggestive Babinski on the right. There was no disturbance in the superficial and deep reflexes. There was no ankle clonus. Funduscopic examination revealed prominent and tortuous veins and early choking of the optic disk on the left. There were no field defects and no nystagmus. Urinalysis was negative; hemoglobin was 14 Gm.; the white blood cell count was 11,800, with 1 stab cell, 59 segmented, 29 lymphocytes and 11 monocytes. Tuberculin and Kline tests were negative. Blood cultures were consistently sterile. Blood pressure ranged between 100 and 110 systolic, 68 to 75 diastolic. During the first three days of hospitalization the temperature was normal but the pulse rate was definitely slow, ranging between 54 and 80 per minute. The patient continued to complain of headache, and vomiting without nausea persisted. On the third hospital day she seemed more drowsy than usual. Despite hypertonic glucose, the drowsiness continued. Quite suddenly on the evening of this day the patient had respiratory difficulty with apnea. The pulse was poor and the skin became ashen gray. She obviously presented a problem of overwhelming increased intracranial pressure. Emergency measures gave only transient relief. Since her general condition was poor and there were no positive signs of localization, ventricular drainage was chosen as the best method to afford maximal relief from the intracranial tension with the least demand on the patient's meager reserves. Accordingly, at 10 p. m. on August 24, under local anesthesia, posterior perforator openings were made over each lateral ventricle. A catheter was introduced into the right lateral ventricle, from which fluid under great pressure was obtained. The patient improved almost immediately, becoming more alert and responsive; the pulse, respiration and color showed improvement.



Ventriculogram, anteroposterior view, Aug 25, 1944, showing displacement of ventricular system to right of midline

Ten hours after the emergency ventricular drainage, ventriculography was performed. A lesion of the left frontal lobe was outlined, as shown in the accompanying illustration. Under local anesthesia a perforator opening was made over the left frontal area. The dura was opened. The dural edges and the exposed cortex were coagulated. An aspiration needle was introduced into the substance of the frontal lobe. No capsule resistance was encountered, but 110 cc. of thick gelatinous pus was aspirated. Sulfanilamide was sprinkled over the cortex, and the wound was closed in layers with silk.

Pus taken from the abscess cavity was studied carefully. Direct smear of this pus showed numerous polymorphonuclear leukocytes and mononuclear leukocytes, but no bacteria were seen. No amebas were noted. The material was cultured on blood agar, aerobically and under reduced oxygen tension, in two separate routine laboratories. In addition, in the Research Laboratory of St. Louis Children's Hospital some of this material was cultured on the chorioallantoic membrane of the developing hen's egg.[3] There was no evidence of bacterial growth on blood agar, but within forty-eight hours a heavy growth of Hemophilus influenzae was noted in the egg. This organism was subcultured with ease from the egg to blood agar. Morphology, staining reaction and cultural characteristics identified the organism as a member of the Hemophilus influenzae group. Numerous typings from the egg and from the blood agar subculture failed to reveal a capsule with A and with B rabbit serum Likewise, a capsular stain failed to show the presence of a capsule. Even after mouse passage, no capsule developed.

In view of the infectious nature of the central nervous system lesion, the patient was given penicillin[3a] 20,000 units at once and 10,000 units subcutaneously every three hours. Sulfanilamide was given, 0.3 Gm. per kilogram of body weight in twenty-four hours. Since fluid intake was restricted during this critical postoperative period, sulfanilamide was used as a temporary measure. After twenty hours, when the fluid intake was more adequate, the chemotherapy was changed to sodium sulfadiazine and later to sodium sulfamerazine. During the period of waiting for encapsulation of the abscess, the patient improved steadily. The wound healed by primary intention On September 11, seventeen days after the initial tapping of the abscess cavity, the patient became increasingly more irritable and drowsy. Headache and vomiting increased in intensity and frequency. The eyegrounds remained essentially the same, and the only suggestive localizing neurologic sign was right facial paresis. These signs suggested that the abscess had refilled.

In order to rule out the possibility of multiple abscesses, ventriculography was performed a second time. The same left frontal deformity was outlined. Accordingly, under local anesthesia the previous perforator opening was enlarged with rongeurs. The dura was sealed off carefully with electrocoagulation. When a ventricle needle was directed gently into the cortex, a firm resistance of the capsule was encountered. The cortex was coagulated and excised with loop cautery down to the capsule. The cortex was dissected away from the capsule with cottonoid. The capsule was incised, and about 180 cc. of pus was aspirated. The capsule was marsupialized to the scalp with chromic sutures and iodoform packs were placed loosely into the depths of the cavity. Sulfanilamide was sprinkled into the wound, and a loose dressing was applied. The patient withstood the procedure satisfactorily.

---

[3] Blattner, R. J.; Heys, Florence M., and Hartmann, A. F.: Advantages of Egg Culture Technic in Infectious Diseases, Arch. Path 36:262 (Sept.) 1943.

[3a] Penicillin was used in conjunction with sulfonamide therapy, since in a case of meningitis a nonencapsulated strain of Hemophilus influenzae was shown to be penicillin sensitive.

On direct smear of the pus obtained, no bacteria were seen. Specimens were sent as before to two separate laboratories, one of which reported the growth on blood agar of a nonhemolytic streptococcus, considered a probable contaminant. The other laboratory reported sparse growth on blood agar of an organism morphologically similar to that isolated previously on the chorioallantoic membrane.

Dressings were changed every two days. The packs were shortened and withdrawn. The capsule gradually extruded itself. Occasional tendency to herniation was controlled with lumbar punctures. The wound closed in gradually and was fully healed at the time of discharge on November 10, two months following the final opening and evacuation of the abscess.

August 25 to October 19, sulfonamide therapy was continued; drug levels ranging from 15 to 22 mg. per hundred cubic centimeters were maintained. In addition, penicillin therapy was given subcutaneously, 10,000 units every two hours from August 25 to September 27.

During the entire postoperative period, the patient showed rapid and steady improvement. She was discharged from the hospital on Nov. 10, 1944, in excellent condition with no evidence of physical, mental or emotional impairment.

COMMENT

A survey of the literature reveals that premortem diagnosis of brain abscess in patients with congenital heart disease is uncommon. However, if brain abscess were considered more generally whenever signs and symptoms of central nervous system involvement develop in a patient with congenital heart disease, the diagnosis would probably be made more frequently. Once the diagnosis of brain abscess is considered, air injection, particularly ventriculography, is of considerable value in establishing the existence and location of the space-occupying lesion. The surgical management of brain abscess must rest with the case in hand and the individual neurosurgeon. In this instance, aspiration followed by surgical drainage was utilized to good advantage. This conservative management seemed necessary in view of the critical condition of the patient. Sulfonamide and penicillin therapy were of great value in controlling the spread of infection. The organism cultured from pus obtained from the abscess was identified as a nonencapsulated influenza bacillus. It is of interest that no organisms were seen on direct smear of the pus obtained on initial aspiration of the abscess and that all cultures of this material except those on the chorioallantois were reported as "sterile." The occurrence of so-called "sterile" pus from brain abscess is not unusual. The fertile egg technic affords a useful method for supplementing the ordinary bacteriologic cultural methods.

In this case the only suggestion of a previous infection which may have etiologic relation with the development of the brain abscess occurred six weeks prior to admission, when the patient had sudden chill and fever. The symptoms abated within twenty-four hours, and no definite diagnosis as to the nature of the infection was made. Two weeks later symptoms referable to the central nervous system were noted. At the time of admission to St. Louis Children's Hospital there was no evidence of infection elsewhere in the body to suggest the site of the primary focus. The pathogenesis in this instance remained obscure, as is often the case with brain abscess. Various theories as to pathogenesis of brain abscess have been suggested. A comprehensive review is included in a recent article by Collis.[4] Frequent attention has been drawn to the presence of sepsis in the lesser circulation, which, by direct passage to the central nervous system, explains the development of brain abscess. The absence of pulmonary infection would seem to make this explanation less likely in the present case.

Diagnosis as to type of congenital heart lesion lay between atypical patent ductus arteriosus and patent interventricular septal defect. While the exact nature of the lesion could not be determined definitely, it was apparent that an arteriovenous shunt existed. The existence of such a congenital heart lesion with arteriovenous shunt suggests a possible mode of pathogenesis. The congenital cardiac lesion presents a possible mechanical arrangement, in view of the mixing of arterial and venous blood and the short-circuiting of the pulmonary bed filter, leading to so-called "paradoxic" embolism. Batson[5] has suggested another conception for the explanation of "paradoxic" embolism. He has drawn attention to the vertebral system of valveless veins which have rich anastomoses with the caval, portal and pulmonary systems. By injection experiments, Batson showed that retrograde embolism to the brain and cranium can occur when intra-abdominal and intrathoracic pressure relationships are modified. According to this view, a brain abscess might result from "paradoxic" embolism even in the absence of congenital heart lesion.

SUMMARY

Symptoms of central nervous system involvement in a patient with a congenital heart lesion suggested the diagnosis of brain abscess. The clinical impression was verified by ventriculography, and surgical treatment was instituted successfully. The organism cultured from aspirated pus was identified as a member of the Hemophilus influenzae group. Sulfonamide and penicillin therapy were regarded as important adjuncts to surgical intervention. The patient has made a complete recovery and is entirely symptom free one year after operation. She shows no personality change and no alteration of mental level.

500 South Kingshighway, St. Louis 10.

Council on Foods and Nutrition

ACCEPTED FOODS

The following additional foods have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association for admission to Accepted Foods.

George K. Anderson, M.D., *Secretary.*

FOODS FOR SPECIAL DIETETIC PURPOSES (See Accepted Foods, 1939, p. 295).

Sunway Fruit Products, Chicago.

Sunway Beverage Base—Orange, Lemon and Lime flavors. Each fruit flavored beverage base contains varying proportions of Powdered Orange Juice Product,* Powdered Lemon Juice Product,* orange oil, lime oil, lemon oil, tricalcium phosphate, F. D. & Co. Dye, anhydrous citric acid, vitamin C, vitamin B_1.

Analysis (submitted by manufacturer).—Ash 1.5%, moisture 2.1%, acidity as citric acid 19% (equivalent to 1.009 liters of normal hydrochloric acid), carbohydrate 78.7%, protein 0.6%, fat 0.183%.

Calories.—1,020 Gm. per 12 ounce can.

Vitamins:

Vitamin B_1	0.065 Gm. per 12 ounce can
Vitamin C	7.700 Gm. per 12 ounce can

When the beverage is reconstituted according to the directions on the can, each 8 ounce serving of finished drink contains:

Calories	116.32 mg.
Vitamin B_1	1.0 mg.
Vitamin C	120.0 mg.

* The Orange and Lemon Powder Products used are those of the Borden Company and are composed of dehydrated citrus juice and powdered corn syrup.

PREPARATIONS USED IN THE FEEDING OF INFANTS (*See* Accepted Foods, 1939, p. 156).

Campbell Soup Company, Camden, N. J.

Campbell's Strained Vegetable Baby Soup, contains tomatoes, carrots, sweet potatoes, white potatoes, peas, onions, oatmeal, okra, celery, salt and water.

Analysis (submitted by manufacturer).—Total solids 13.4%, protein 1.95%, fat 0.5%, carbohydrate by difference 9.3%, crude fiber 0.43%, calcium 0.024%, phosphorus 0.051%, iron 0.73 mg. per hundred grams, copper 0.24 mg. per hundred grams, manganese 0.018 mg. per hundred grams.

Calories.—14 per ounce.

Vitamins.—

Vitamin A	2,550 I. U. per hundred grams
Thiamine	0.069 mg. per hundred grams
Riboflavin	0.064 mg. per hundred grams
Ascorbic acid	7.5 mg. per hundred grams
Niacin	1.05 mg. per hundred grams

Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, JANUARY 19, 1946

DEATHS OF PHYSICIANS IN 1945

The obituaries of 2,962 physicians were published in The Journal during 1945. The American Medical Directory Report Service recorded 3,815 deaths in the United States, possessions and temporary foreign, or 853 more than were published in The Journal. In addition approximately 200 notices of deaths had been received but not yet published, giving a total of 4,015 deaths for an overall consideration. The present analysis, however, is concerned only with the 2,962 deaths published.

Under the accelerated program up to June 30, one class of 5,136 students was graduated in medical schools in the United States in 1945. Deducting the 4,015 deaths, an estimated net increase to the profession of 1,121 is noted. Overlapping totals are recorded, since deaths in years other than 1945 are included in this analysis for the current year. Increases in the profession due to the accelerated medical school program are not reflected in these figures, since it was in the year 1944 that most medical schools graduated two classes.

Age.—The average age at death was 65.3 in 1945 as compared with a similar age in 1944. Sixty-nine physicians died between the ages of 25 and 29, 88 between 30 and 34, 66 between 35 and 39, 101 between 40 and 44, 117 between 45 and 49, 168 between 50 and 54, 245 between 55 and 59, 330 between 60 and 64, 464 between 65 and 69, 494 between 70 and 74, 390 between 75 and 79, 246 between 80 and 84, 139 between 85 and 89, 31 between 90 and 94, 11 between 95 and 99 and 3 aged 100 or over.

Causes.—Heart disease continues to lead the causes of death among physicians. As is customary in compiling these statistics, primary causes and contributory factors were included. Coronary thrombosis and occlusion accounted for 655; 246 occurred in the ages between 60 and 69. Diseases of the myocardium and pericardium accounted for 146 deaths, angina pectoris and other coronary diseases 121, chronic heart valvular disease and rheumatic heart disease 21, subacute bacterial endocarditis (except rheumatic fever) 11 and other diseases of the heart 330. Cerebral hemorrhage, thrombosis and embolism were responsible for 335 deaths, arteriosclerosis for 150 and cardiovascular diseases for 76. Cancer and tumors accounted for 296, 151 of which were classified under cancer of the gastrointestinal tract. One hundred and forty-five deaths were attributed to pneumonia, of which 4 were atypical or virus pneumonia. Asthma caused 13 and bronchitis and pleurisy 6 deaths. Chronic nephritis and uremia accounted for 114 and acute nephritis for 15. Diseases of the circulatory system caused 66 deaths, diabetes 44, Hodgkin's disease and leukemia 26, pernicious anemia 12 and other diseases of the blood 7, diseases of the gastrointestinal tract 29, cirrhosis of the liver 20 and other diseases of the liver 6, tuberculosis 19, diseases of the respiratory system 30, peptic ulcer (ulcer of the stomach and duodenum) 18, peritonitis 11, influenza 6, pulmonary embolism and thrombosis 12 and other embolism and thrombosis 22, diseases of the genitourinary tract 10, aneurysm 10, diseases of the gallbladder, bile duct and cholecystitis 14, diseases of the nervous system 23, mental disease and diseases of the brain 4 each, diseases of the prostate 27, asthma 13, chronic arthritis 8, appendicitis, encephalitis and meningitis 5 each, diseases of the bones and organs of locomotion and osteomyelitis 4, diseases of the thyroid and alcoholism 3 each, abscess and other infectious diseases 2, bacteria, septicemia and pyemia 2, hernia 1, syphilis 1 and diseases of the spinal cord 1. There were 29 deaths following operation. One death each was attributed to epidemic hepatitis, "constitutional shock due to hapamine," Addison's disease, pellagra, typhus, undulant fever, mushroom poisoning and typhoid. Senility was returned as the cause of death in 34 instances, while the cause of death was ill defined in 7.

Suicides and Homicides.—Of the 25 suicides recorded 11 deaths were the result of bullet wounds, 3 of a cut artery and 3 of drugs. One death each was attributed to carbon monoxide, gas, hanging, jumping, drowning, alcoholism, barbiturate intoxication and leaping in front of a train. The method was not obtained in 1 suicide. Shooting was the method used in the 2 homicides reported,

Accidental Deaths.—Of the 87 accidental deaths, automobiles were involved in 33, 1 of which was caused by an automobile and train crash. Of the unusual accidents 1 physician died of burns received when his clothing became ignited from a cigar that he had been smoking when he fell asleep, 1 died in a hunting accident when his gun went off as he was handing it to a fallen companion, 1 of accidental phenobarbital poisoning, 1 of fractured ribs when he fell beneath a farm machine and 1 when he accidentally fell from a cliff.

Miscellaneous Positions.—Among the decedents were 256 who had been teachers in medical schools, of whom 97 had reached professorial status. There were 8 deans, 1 of whom had also been president of a medical college, 2 principals of a high school, 2 teachers in public schools, 1 of whom had been head of the business and practice department of the District of Columbia high schools, and 78 members of education boards. One hundred and forty-four had been health officers, 94 members of health boards and 16 members of medical examining boards. Fifty-nine had been coroners, 54 mayors, 27 pharmacists, 23 bank presidents, 13 police physicians or surgeons, 11 missionaries, 7 postmasters, 6 druggists, 5 dentists, 4 lawyers, 1 a city alienist and 1 a police commissioner. There were 39 authors and 21 editors. There were 14 members of legislatures, 1 of whom was a member of the United States Senate. One physician once served as minister to Liberia. In the various military connections, 1 had served in the Boer War, 2 in the Boxer Rebellion, 5 in the Civil War, 2 in the Philippine Insurrection and 516 in World War I. One each had been in the Austrian, German, Hungarian, Greek and Russian imperial armies and 3 in the British army.

Association Officers.—The decedents included 2 who had been Vice President and 3 members of councils, 1 of whom had been chairman and 1 member of the Judicial Council. There were 13 who had been section officers and 34 who had served as members of the House of Delegates. Twenty-nine had been presidents of their state medical societies, 1 president-elect, and 178 had been president of their county medical societies.

Killed in Action

The 2,962 obituaries included 116 physicians who were killed in action during World War II and 118 who died while in military service. Specific information was not available as to the type of death of those killed in action in the general group. Some reports indicated mine explosion, multiple wounds, gunshot wounds, explosion of bombs and fragment shell wounds. A number had first been reported missing in action and subsequently given a presumptive date of death. The following locations as those where injuries resulting in death occurred are noted as received in official reports: Pacific area 19, Germany 13, European Theater of Operations and France 12 each, Okinawa 11, including 6 who were lost in the attack on the *Comfort,* Belgium 8, Asiatic area 7, Luzon 6, South China Sea 5, Italy 4, Africa 3, Io Jima and Mindanao 2 each and the Netherlands, Marianas, Salerno, Austria, China, North America area, Atlantic area, Isle of Capri, Yugoslavia and Algeria 1 each. Two of this group died while prisoners of the German government, 1 when his ship was lost off the coast of the New Hebrides and 1 when his ship was lost en route to Iraq. Thirty-nine died in the ages between 25 and 29, 39 between 30 and 34, 22 between 35 and 39, 10 between 40 and 44, 4 between 45 and 49, 1 between 50 and 54 and 1 between 55 and 59.

Died in Military Service

Of the 118 physicians who died while in military service, aircraft accidents caused the deaths of 22 and vehicle accidents of 10. Heart disease accounted for 25 deaths, 12 of which were attributed to coronary thrombosis. Carcinoma caused 13 deaths. In the remaining deaths from miscellaneous causes, 1 physician died of poliomyelitis and 3 of infectious hepatitis. Two deaths followed an operation. Gunshot wounds led the suicides with 4 deaths, hanging caused 2 and cut artery, acute morphine poisoning, barbiturate poisoning and "no method" 1 each. Eighteen died while in military service between the ages of 25 and 29, 31 between 30 and 34, 14 between 35 and 39, 21 between 40 and 44, 12 between 45 and 49, 6 between 50 and 54, 10 between 55 and 59, 4 between 60 and 64, 1 between 65 and 69 and 1 between 70 and 74.

Of the seven U. S. Public Health Service officers whose deaths were recorded, 1 died when he slipped on the Jacob's ladder while assisting wounded aboard ship, 1 when his ship was destroyed in enemy action, 1 as a suicide, 1 of coronary thrombosis, 1 of heart disease and 2 of cerebral hemorrhage. One died between the ages of 25 and 29, 1 between 30 and 34, 2 between 40 and 44, 1 between 50 and 54, 1 between 60 and 64 and 1 between 65 and 69. There was 1 Merchant Marine casualty, aged 64.

The 116 deaths classified killed in action give an average age of 33.0, while the 118 who died while in military service give 40.1. Combining the 2, an average age of 36.6 is noted. Deducting this group from the general total of 2,962 deaths, an average age of 67.7 is reported. This figure must be interpreted with great care, however, since a proportion of the young physicians who died in service would have undoubtedly died from other causes had they remained in civilian life.

Since the outbreak of the war The Journal has recorded the obituaries of 217 physicians who died in action and 373 who died while in military service. The Journal again emphasizes that the aggregate total of 590 deaths represents only a percentage of the total to be released eventually through official military channels. The Journal will continue to publish these reports as they are received.

THE ONSET AND SPREAD OF POLIOMYELITIS

The method by which poliomyelitis is transmitted from one person to another has long been a subject of active investigation. Recently emphasis has been placed on the environmental and sanitary settings, for the virus can be isolated from sewage, privies, stagnant water and flies caught in polluted areas. The virus may remain inactive in such nonhuman reservoirs for several months and even then be experimentally activated by being transferred to monkeys, but it has not been established that the virus from such an environment gives rise to human poliomyelitis, although the possibility of transmission to human beings from nonhuman sources undoubtedly exists. A large body of facts is now available, however, indicating that the disease is passed from person to person by respiratory and oral transfer; these facts have been considerably reinforced by two recent studies of epidemics observed in Chicago and Buffalo.

The Chicago investigations by Casey and his associates,[1] using material from a large urban community during a nonepidemic year, may be contrasted with a similar report by Casey [2] on patient to patient contact in a rural area during a severe epidemic in Alabama in 1941. The two studies reached practically the same conclusions. The incubation period from the time of exposure to the onset of the prodromal period was from four to thirty-five days, averaging twelve days, with the infectious period lasting three days before or three days after the onset of the prodromal period. Evidence was produced, moreover, establishing at least 80 per cent patient to patient contact in the Alabama epidemic, a similar rate being reported in the Chicago studies. To achieve this figure cases were counted of "illnesses compatible with poliomyelitis." The study was favored by the hospitalization of 230 out of 233 cases during the Chicago epidemic, and the diagnosis in the nonparalytic group was based on a history of a febrile illness, contact with known cases and the finding in the spinal fluid of an elevation of protein to 45 mg. per cubic millimeter or above. With such cases included, multiple cases in the family were the rule rather than the exception and poliomyelitis was found to be, in the Chicago cases, contagious to the degree of 90 per cent in the 1½ to 3½ age group. Paralysis developed in about 1 case in 6.

The Chicago study thus brings to attention the high rate of patient to patient contact in poliomyelitis when fully investigated cases of minor illnesses, particularly by either daily thermometer readings or retrospective spinal fluid examinations or both, are taken into consideration. Until serologic or other inexpensive laboratory tests are available, the diagnosis of poliomyelitis in children without paralysis must rest on such criteria.

The 1944 epidemic in the Buffalo area offered opportunities, as did the Chicago epidemic of 1945, to study the relative importance of the environmental and human reservoirs of the virus in initiating an epidemic. Smith [3] and her associates found that the first 3 paralytic cases in the epidemic did not arise "de novo" but were part of a cycle of poliomyelitis which had been in progress but unsuspected for approximately three months. The incidence of illnesses in the community, moreover, which were highly suggestive of the nonparalytic forms of the disease was at least five times the number of recognized cases. Poliomyelitis tended to develop in a setting of minor illnesses, which, when carefully analyzed, appeared similar to those caused by the virus of the disease. These unrecognized cases formed a human reservoir, and the virus appeared to be continuously active between epidemic periods. Based on these findings, Smith believes that the concept of what constitutes an epidemic of infantile paralysis should be broadened, for an "epidemic" of poliomyelitis may well be under way long before paralytic cases are recognized.

As in the report by Casey, the Buffalo investigators found that the evidence pointed predominantly toward a person to person transfer of the virus, most likely by means of respiratory or oral reactions rather than a transfer by flies. Although the general environmental factors in transmission of poliomyelitis cannot be entirely disregarded, these recent studies tend to stress the direct person to person transfer as the most likely mode of spreading the disease.

Current Comment

EFFECT OF INDUCED JAUNDICE IN RHEUMATOID ARTHRITIS

The appearance of jaundice in the presence of rheumatoid arthritis generally brings about a distinct remission of the arthritic symptomatology. Most recent of the studies on the subject is that by Gardner and her colleagues [1] of Oxford. A total of 312 patients with polyarticular arthritis of the rheumatoid type were given material from cases of infectious hepatitis. Only 32 of the inoculated patients developed jaundice. Of the patients successfully inoculated, the interval between the time of inoculation and the appearance of jaundice varied from twenty-seven to one hundred and thirty-one days. Ten patients became completely free from pain in all their joints; frequently free movement was restored and the joint swellings disappeared; 8 patients became free from pain in many but not all affected joints, the periarticular swellings diminished and mobility was greatly increased; 7 patients obtained some relief from pain and swelling with increased improvement; the joint condition of 7 patients was unaltered. Definite relationship between the intensity of jaundice and type of remission could not be shown. The greatest degree of improvement averaged forty-two days, but a much longer time usually elapsed before the joints relapsed to the condition existing prior to the introduction of jaundice. Studies of the blood sedimentation rate indicated that the jaundice materially interferes with the value of this test as a reflection of activity of the arthritic process; usually there was an abrupt fall in the blood sedimentation rate after the appearance of jaundice. An increased rate above the original value commonly occurred after two or three months, during the period in which the arthritic symptoms remained improved. The remissions produced by the British investigators, as well as those which have been reported by others, have been temporary. Treatment of rheumatoid arthritis by attempting to induce jaundice is not recommended. The procedure is justifiable in the treatment of patients with rheumatoid arthritis only as a possible means of controlled research with the allied possibility of analyzing the mechanism by which such remissions are produced.

PACIFIC VIVAX MALARIA TRANSMITTED BY ANOPHELES QUADRIMACULATUS

Malaria carriers among personnel of the armed services returning to this country from Pacific combat areas will be widely distributed throughout our country. Some of them will come in contact with anopheline mosquitoes in regions where malaria has been unknown for many years as well as in places where malaria is endemic. The prevalence and course of malaria infection in personnel originating from malarious areas compared with similar data for personnel from nonmalarious locations should be studied. The transmission of imported strains of malaria by indigenous anophelines is of much epidemiologic importance. R. B. Watson[1] in a recent study determined that Pacific strains of Plasmodium vivax can be transmitted by Anopheles quadrimaculatus. From soldiers who had presumably acquired their infections in Pacific war areas, six strains of vivax were isolated by transfer of blood to patients who were to receive malaria therapy. The induced infections were not unlike those produced by the McCoy strain of P. vivax. Some of the patients with known or probable histories of former vivax infections demonstrated immunity to the Pacific strain infections, contrary to the general belief that tolerance conferred by vivax infection is largely homologous. Anopheles quadrimaculatus mosquitoes were fed on these patients with induced malaria when gametocytemia favored mosquito infection. Salivary gland dissections of these mosquitoes demonstrated infections for three of the six Pacific vivax strains. For two of these strains it was found that low densities of gametocytes could infect mosquitoes. Watson concludes that "at least some of the Pacific vivax strains can be transmitted by A. quadrimaculatus."

POSTMORTEM EXAMINATIONS AND THE JEWISH LAW

Because of the undesirability of some resistances against postmortem examination that appear among the relatives of Jewish patients who die, Dr. I. M. Rabinowitch,[1] special lecturer in medical jurisprudence at McGill University, Montreal, recently investigated the laws with regard to postmortem examination contained in the Bible and in the Talmud. He points out that the attitudes of non-Jewish people of the same period toward postmortem examinations were much the same as those of the Jewish people. Arguments in favor of prohibiting postmortem examinations are based on four authentic instances in which a requested postmortem examination was prohibited by a celebrated rabbi. However, Rabinowitch points out that permission was refused in each instance because of the argument that the postmortem examination would not be of any value either in clearing the cause of death or of any benefit to the living. The thorough search which Rabinowitch has made convinces him that nowhere in the Bible, in the Talmudic, in the post-Talmudic or in the later Rabbinical writings is there any evidence that postmortem examinations are prohibited by Jewish law. Indeed such prohibition would be inconsistent with the fundamental directing principle in Judaism—"The Laws were given that man shall live by them, not that they shall die by them."

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

The first peacetime Congress on Medical Education and Licensure in five years will be held in Chicago February 11 and 12. The program appears elsewhere in this issue. The difficult problems of wartime medical education and licensure, which were met and solved with determination, have left an aftermath of reconversion problems of considerable magnitude. Some of these will be presented in the papers and discussions of the formal program. Many others will be the concern of groups affiliated with the Council on Medical Education and Hospitals of the American Medical Association, which regularly hold sessions at the time of the congress. Such groups include the Association of American Medical Colleges, the Advisory Board for Medical Specialties, the National Board of Medical Examiners and several others. Further delay in making hotel reservations is not safe. Communications to the Palmer House should be addressed to Mr. R. L. Collison, mentioning the Congress on Medical Education and Licensure, to insure the best service. Other nearby hotels are the Stevens, Blackstone, La Salle, Morrison, Continental and Congress.

MEDICINE AND THE WAR

ARMY

BRIG. GEN. RAYMOND W. BLISS NAMED DEPUTY SURGEON GENERAL

Brig. Gen. Raymond W. Bliss was recently appointed Deputy Surgeon General to succeed Major Gen. George F. Lull, who retired after thirty-three years of service in the Medical Department. In addition to his new responsibilities, General Bliss will continue to serve as assistant Surgeon General and Chief of Operations Service. He was recently awarded the Distinguished Service Medal (The Journal, Dec. 29, 1945, p. 1265).

General Bliss became Chief of Operations Service in the Office of the Surgeon General, Washington, D. C., in June 1943 and in August 1944 was made Assistant Surgeon General. He graduated from Tufts College Medical School, Boston, in 1910 and was commissioned in the Army Medical Reserve Corps in 1911.

REFRESHER COURSES FOR ARMY DOCTORS

Major Gen. Norman T. Kirk, Surgeon General of the Army, announced recently that refresher training courses covering twelve weeks will be offered to doctors leaving the service in the fields of medicine, surgery and neuropsychiatry. The program will be available until June 30 at army hospitals to reserve corps, National Guard and medical corps officers scheduled to leave the service.

Such a refresher course would provide temporary duty assignment at a hospital where the medical officer would have clinical work under supervision and opportunity for study of recent advances in medicine.

CANADIAN SURGEON GENERAL VISITS OFFICE OF THE SURGEON GENERAL

Major Gen. C. P. Fenwick, director general of medical Services, Royal Canadian Army Medical Corps, recently completed an inspection tour of the various divisions of the Office of the Surgeon General of the Army. The purpose of his visit was to make a first hand study of the organizational plans for the medical department of the postwar army with the aim of preparing similar plans for the Canadian army. During his stay, General Fenwick also inspected installations at the Army Medical School, Walter Reed General Hospital and several naval medical installations in Washington.

AVIATION MEDICAL EXAMINERS

Sixty-four medical officers recently completed the aviation medical examiners' course at the A. A. F. School of Aviation Medicine, Randolph Field, Texas. Brig. Gen. Eugen G. Reinartz, commandant of the school, presented the graduation awards to the first peacetime class of flight surgeons. These medical officers, specially trained in the phases of aviation medicine dealing with the care of fliers and combat crewmen, will become flight surgeons on completion of additional training.

FRENCH MEDICAL OFFICERS PLAN TO VISIT ARMY MEDICAL INSTALLATIONS

Three French medical officers, Commandant Louis Pages, Commandant Francis Borrey and Commandant Arquie, are making plans to spend four months in the United States, seven and a half weeks of which will be spent in touring Army Medical Department installations. The itinerary includes a ten day stay at Moore General Hospital, Swannanoa, N. C., for the study of methods of treatment of tropical diseases and a three week study at the laboratories and in organization and treatment at Walter Reed General Hospital, Washington, D. C. They plan also to visit the Food and Nutrition Laboratories, Chicago, for a two week observation of research in nutrition and food packaging. A week's study will be spent at Fort Bragg, North Carolina, for an observation of methods of treatment employed there. A discussion of findings at the U. S. Respiratory Laboratory and observation of water and sewerage systems will conclude their trip.

ARMY AWARDS AND COMMENDATIONS

Colonel Herbert C. Gibner

The Legion of Merit was recently presented to Col. Herbert C. Gibner, formerly of Washington, D. C.: Accompanying the award was a citation explaining that "Col. Herbert C. Gibner, Medical Corps, as surgeon of the Seventh Corps Area, later designated the Seventh Service Command, from September 1940 to December 1943 solved the complex medical problems of the command in an outstanding manner during a period of mobilization, rapidly expanding garrisons and changing organization. He swiftly evaluated the general status and availability for active service of approximately four thousand medical department reserve officers and supervised the reorganization of the command's medical department in line with that of the Army. His comprehensive understanding of the exacting requirements and technical details of the medical service, his skill, leadership and mastery of staff relationship, won high regard for the medical section of command headquarters and the service in the field. His exceptional ability as a teacher was so widely recognized that service under his supervision was sought by many medical officers. Colonel Gibner made a major contribution to the efficient operation of the Seventh Service Command" Dr. Gibner graduated from Yale University School of Medicine, New Haven, Conn., in 1903 and entered the service May 1, 1905.

Major Walter W. King

Major Walter W. King, formerly of Peoria, Ill., was recently awarded the Bronze Star medal at Winter General Hospital, Topeka, Kan., where he is now stationed as chief of the surgical service. The citation accompanying the award emphasized his "meritorious service in connection with military operations against the enemy as surgeon, general surgical team No. 5, third auxiliary surgical group, from June 6, 1944 to October 16, 1944, in France and Belgium. Although the arrival of medical equipment and supplies was delayed during the landing of his surgical team on the invasion beach on D day, Major King, displaying outstanding initiative and marked professional ability, organized his group and gave immediate treatment to battle casualties. During subsequent operations he displayed tireless effort and worked many hours each day to bring expert medical service to seriously wounded patients." Dr. King graduated from Northwestern University Medical School, Chicago, in 1930 and entered the service Aug. 26, 1942.

Lieutenant Colonel Rudolph N. Schullinger

Lieut. Col. Rudolph N. Schullinger, formerly of New York, was recently awarded the Legion of Merit for "unusual service in the distribution of penicillin through the various base hospitals in England and for the establishment of a hospital in France, following the invasion." Recently returned from Europe, where he was chief of surgery of the Churchill Hospital, Oxford, England, Colonel Schullinger has now been assigned to the staff of the Halloran General Hospital. Dr. Schullinger graduated from Columbia University College of Physicians and Surgeons, New York, in 1923 and entered the service Feb. 15, 1942

Captain R. L. Wall Jr.

Capt. Roscoe L. Wall Jr., formerly of Winston-Salem, N. C., was recently awarded the Bronze Star Medal for outstanding achievement. His citation reads, in part, "Captain Wall, as surgeon of Headquarters Squadron, Ninth Air Defense Command, rendered invaluable service to the personnel of the headquarters. He worked tirelessly day and night to provide medical attention for the squadron, cheerfully accepting any additional burdens which arose. At the same time, when his staff was depleted by transfers, he trained new personnel and reorganized the action. The professional knowledge, initiative and devotion to duty displayed by Captain Wall reflects the highest credit on himself and the armed forces of the United States." Dr. Wall graduated from Jefferson Medical College of Philadelphia in 1940 and entered the service Nov. 16, 1942.

Colonel Joseph A. Crisler Jr.

The Legion of Merit was recently awarded to Col. Joseph A. Crisler Jr., formerly of Memphis, Tenn., for meritorious services. The citation accompanying the award read, in part, "Demonstrating professional skill and sound judgment, Colonel Crisler capably supervised the activities of his auxiliary surgical group. His superior leadership was reflected in the exceptional work performed by his organization in First Army and evacuation hospitals. . . . Colonel Crisler's extraordinary ability and careful attention to detail contributed directly to the saving of many lives, reflecting highest credit on himself and the military service." Dr. Crisler graduated from Harvard Medical School, Boston, in 1921 and entered the service Sept. 8, 1942.

Lieutenant Colonel I. Herbert Scheffer

The Bronze Star was recently awarded to Lieut. Col. I. Herbert Scheffer, formerly of New York, for "meritorious service in connection with military operations as chief of the Public Health Section headquarters, European Theater of Operations, from Aug. 26, 1944 to May 8, 1945. Lieutenant Colonel Scheffer observed, reported and took necessary action relative to civilian public health conditions in the Paris area as far as the interests of the Allied armed forces were concerned. By his prompt action and superior professional skill he was instrumental in the elimination of numerous health hazards in the area, in keeping to a minimum the incidence of contagious diseases and in correlating the turnover of civil affairs. Colonel Scheffer's accomplishments reflect the highest credit on himself and the armed forces of the United States." Dr. Sheffer graduated from McGill University Faculty of Medicine, Montreal, in 1925 and entered the service Aug. 12, 1942.

Captain Maurice L. Malins

The Soldier's Medal was recently awarded to Capt. Maurice L. Malins, New York, in company with others, for "heroism displayed at U. S. A. A. F. Station 493 on March 4, 1944. When a P-38 type aircraft crashed in flames on the edge of a deep ravine, these members of the 315th Troop Carrier Group, realizing the urgency of effecting a prompt rescue of the pilot, hastened to the scene of the accident and, disregarding the pilot's warning that the aircraft was in imminent danger of exploding, gallantly struggled to extricate the trapped pilot, and, when his release had been effected, assisted in extinguishing the flames. By their prompt and courageous action they were successful in saving the pilot's life, and their unhesitating devotion to duty reflects great credit both to themselves and to the service." Dr. Malins graduated from McGill University Faculty of Medicine, Montreal, in 1932 and entered the service May 21, 1941.

Captain William J. Slaughter

Capt. William J. Slaughter, formerly of Meridian, Miss., was recently awarded the Bronze Star for meritorious achievement in battle. The citation states that Captain Slaughter, with the fighting 41st through the bloody action in the Netherlands East Indies and the more recent heavy battles of the Philippines, distinguished himself by his courage and bravery. His untiring devotion to duty won for him the respect of his fellow doctors and the deepest gratitude of the men he helped." Dr. Slaughter graduated from the University of Tennessee College of Medicine, Memphis, in 1937 and entered the service Nov. 1, 1940.

MISCELLANEOUS

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

ILLINOIS

MacNeal Memorial Hospital, Berwyn. Capacity, 210; admissions, 6,350. Mr. F. J. McCarthy, Administrator (residents—mixed service, now and April 1).

Illinois Masonic Hospital, Chicago. Capacity, 186; admissions, 5,280. Mr. William H. Tenney, Superintendent (resident—medicine).

IOWA

Broadlawns, Polk County Hospital, Des Moines. Capacity, 295; admissions, 3,044. Mr. T. P. Sharpnack, Administrator (3 interns, July 1).

MASSACHUSETTS

Memorial Hospital, Worcester. Capacity, 215; admissions, 7,713. Dr. Winthrop B. Osgood, Medical Director (2 interns).

NEBRASKA

Lincoln General Hospital, Lincoln. Capacity, 223; admissions, 5,649. Mr. Robert B. Witham, Administrator (4 interns, July 1—male or female; resident—mixed service).

NEW YORK

Beth Moses Hospital, Brooklyn. Capacity, 215; admissions, 5,268. Mr. J. Goodfriend, Executive Director (interns, February to October).

NORTH CAROLINA

James Walker Memorial Hospital, Wilmington. Capacity, 331; admissions, 8,636. Mr. George R. Darden, Assistant Superintendent (interns, April 1).

UTAH

St. Mark's Hospital, Salt Lake City. Capacity, 245; admissions, 5,121. Dr. R. M. Muirhead (2 interns).

WASHINGTON

Northern Permanente Foundation Hospital, Vancouver. Capacity, 360; admissions, 11,087. Dr. J. W. Neighbor, Medical Director (interns, April 1 and July 1).

COST OF HEAVY CARBON TO BE CUT NINETY PER CENT

The cost of heavy carbon, used by scientists, for example, to follow the course of sugar or other foods in the body, will be cut from $400 a gram to approximately $40, as a result of a recent industrial development. The plant which will produce heavy carbon (carbon 13, as it is sometimes called) so that its cost will come down is to be built by the Sun Oil Company and the Houdry Process Corporation. The new plant will consist of a series of four or five towers 90 to 100 feet high, will cost approximately $100,000 and will produce about 500 Gm. of carbon 13. Its availability in larger amounts and at a lowered cost will make possible further progress in research on cancer, diabetes and arteriosclerosis. This material can also be used to grow vegetables which would provide the tracer elements through which scientists can watch the ultimate absorption of the food into the body cells.

COURSE OFFERED TO DISCHARGED MEDICAL OFFICERS

Harvard Medical School, Boston, will offer a six months refresher course to medical officers discharged from the armed forces. The first course will begin February 1. The course will emphasize current scientific knowledge and theories and advances in the medical field and will be under the supervision of Eugene C. Eppinger, assistant dean.

Dillon, Roll N., Major, 1618 20th N., Seattle.
Lowenstein, Bernard, Major, Tacoma Indian Sanat., Tacoma.
McElroy, Donald M., 1st Lt., 732 N. Stadium Way, Tacoma.
Nelson, Averly M., Capt., Route 2, Wenatchee.
Roe, James A., Capt., 504 Percival St., Olympia.
Sims, William F., Capt., 1409a W. Yakima, Yakima.
Tennant, Raymond E., Lt. Col., 1227 Med. Dental Bldg., Seattle.

Wisconsin

Anderson, Lawrence L., Major, Wisconsin Gen. Hosp., Madison.
Doolittle, John W., 1st Lt., 130 Breese Terrace, Madison.
Mann, Robert W., Capt., 2863 N. Lake Dr., Milwaukee.
Ottenstein, Harold H., Capt., 2760 N. 11th St., Milwaukee.

CHANGES

Archer, George Ferguson, Capt., 21 Peachtree Memorial Dr., Atlanta, Ga. Reported week 11-2-45.
Ascher, David, Major, 1657 Commonwealth Ave., Boston, Mass. Reported week ending 11-30-45.
Dreier, Joseph Francis, Major, P. O. Box 30, Dushore, Ga. Reported week ending 10-26-45.
Fisher, Edward Johnston, Capt., 807 Spruce St., Philadelphia, Pa. Reported week ending 11-2-45.
Frazier, John Wesley, Lt. Col., Salisbury, N. C. Reported week 10-12-45.
McKibbin, John Philip, Capt., 430. 7th St. S.W., Rochester, Minn. Reported week 11-30-45.
Newman, William Harris Jr., Major, Clark's Green, Pa. Reported week 10-19-45.
Phillips, Water Aills, Lt. Col., Arlington, Tenn. Reported week ending 9-21-45.
Wickard, Charles Phillip, Capt., 2809 Gaines St., Little Rock, Ark. Reported week 10-19-45.
Zink, Linus Anthony, Major, Pecos, Texas. Reported week ending 9-21-45.

Foregoing listed officers have been recommended for return to active duty.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Jan. 14, 1945.

Dangers of Biologic Warfare Stressed in Report

George W. Merck, president of the Merck Chemical Company and special consultant to the Secretary of War, states in a special report presented to Secretary of War Patterson that biologic warfare, the spread of infection and disease, may become a greater threat to the peace of the world than the atomic bomb. This was the opinion of the group of scientists who compiled the report after more than four years of work on the subject, carried on in complete secrecy. It was also revealed that American scientists had feared an outbreak of germ warfare at the time of the landing in Normandy but were ready for it. The Navy announced that it had developed protective rubberized germ proof suits.

Capital to Exterminate Rats as Safeguard Against Typhus

Typhus has stricken a 16 year old girl and typhus infested rats have been caught in Washington, with the result that the District of Columbia has launched a campaign to clear out its notorious rat nuisance. Dr. John Essex, Public Health Service expert of Atlanta, Ga., has been brought in and latest scientific methods, including experiments with DDT and the new rat poison 1080, will be used. The District of Columbia public health engineer declared that swift action is required "if we're to ward off a typhus outbreak. It's raging down south and we can't allow it to spread here."

Subcommittee to Redraft Unification Bill

A new draft of the administration's Army-Navy unification bill, which involves medical branches of the armed forces, is to be worked out by a three man subcommittee of the Senate Military Affairs Committee. An effort will be made to speed up action when Congress resumes, January 14. Senate Military Chairman Elbert D. Thomas, Democrat of Utah, will head the subcommittee. The completed bill is expected to follow President Truman's recommendation for a single department under one cabinet head, with coordinated Army, Navy and Air arms, each under an assistant secretary.

Army Tablets Go Back to Manufacturers

The Surplus Property Administration reports that surplus amphetamine sulfate tablets, declared by the U. S. Food and Drug Administration to be extremely dangerous if distributed as at present packaged and if not used under medical supervision, will be sold back to the original manufacturer. The tablets from military medical stocks were declared surplus and will be sold to Smith, Kline and French Laboratories of Philadelphia, the manufacturers, at not less than the original cost to the government for repackaging and resale.

Veterans Administration Hires Specialist on Medical Problems of Women

For the first time in its history, the Veterans Administration has hired a special consultant on medical problems of women. Gen. Omar N. Bradley announced the appointment of the new post of Lieut. Col. Margaret D. Craighill, specialist on gynecology and surgery, who has served as consultant for women's health and welfare to the Surgeon General of the Army. She entered the Medical Corps in 1943 as a major.

Shortage of Housing Feared Menace to National Health

Washington officialdom, fearful that the current national shortage of housing might menace health, is getting help from the armed forces. The Navy has moved to provide some relief by declaring surplus $56,000,000 worth of building materials and 5,000 quonset huts located at four depots in the United States. The barracks could house an estimated 70,000 persons.

Council on Medical Service and Public Relations

PREPAID MEDICAL CARE NEWS

Yonkers Experiment

A recent experiment of United Medical Service, Inc., and Associated Hospital Service of New York should show rather definitely how interested people are in protecting themselves against the costs of medical care. On November 26 these two organizations started on a two weeks campaign to interest the citizens of Yonkers in the prepayment plan idea.

Six enrolment offices were located in business organizations and libraries throughout the city. Posters in these offices, in railway stations and at other prominent locations set forth the objectives of the campaign "to enable every person under 65 years of age who lives or works in Yonkers to enroll in the prepaid plans." During the period of the campaign, persons who were self employed, unemployed or otherwise unable to enroll through a group were given the privilege of enrolling without having to file a medical questionnaire.

Information concerning the campaign was also made available to the public through a series of paid announcements in the local press and through the voluntary cooperation of the city's medical societies, hospitals, welfare organizations and business and professional groups. For instance, Mayor Curtis E. Frank, on the opening day, issued a proclamation sponsoring the campaign. Girl and Boy Scouts helped to distribute literature and set up window displays. The Yonkers Medical Society passed a resolution endorsing the campaign. Official endorsements were also voted by such organizations as the common council of the city of Yonkers, the Social Planning Council, the Yonkers Teachers Association and the Yonkers Department of Public Health.

These endorsements, together with day by day progress reports, were fully reported in the press. Commentators broadcast the details of the campaign over the radio. People attending their places of worship heard announcements from the pulpit. The board of education cooperated by granting the committee permission to distribute Blue Cross and United Medical Service literature to students of public and parochial schools. Each set of literature, accompanied by a form letter addressed to the parents, was placed in an envelop which the pupils were urged to take home. A letter from the superintendents to the principals suggested that the pupils be advised of the importance of the literature. In some schools additional letters were sent by the principal to the parents.

Thousands of people learned about the campaign at local movie houses, where the film "Every Two Seconds," with a campaign trailer attached, was shown. Every theater in town cooperated.

Thousands more heard speakers explain the hospitalization and medical care plans at meetings of the Business and Professional Women's Club, the Exchange Club and the Visiting Nursing Association and at special gatherings such as one arranged by the Yonkers *Herald Statesman* for the benefit of its employees.

The Yonkers Medical Care Committee, comprising prominent Yonkers residents and business men, was appointed by the common council of Yonkers to conduct the campaign with the cooperation of Associated Hospital Service of New York and United Medical Service, Inc., after a two year study of existing medical expense plans. All communications to the public and press were issued on specially prepared committee letterheads under the signature of the committee chairman.

MEDICAL EDUCATION AND LICENSURE

Forty-Second Annual Congress on Medical Education and Licensure, to be held in the Red Lacquer Room, Palmer House, Chicago, February 11 and 12, 1946

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS, AMERICAN MEDICAL ASSOCIATION

MONDAY MORNING, 9:30

RAY LYMAN WILBUR, M.D., *Presiding*

Address
RAY LYMAN WILBUR, M.D., Stanford University, Calif., Chairman of the Council on Medical Education and Hospitals

IMPACTS OF THE WAR ON MEDICINE

Medical Progress During the War
PERRIN H. LONG, M.D., Baltimore, Professor and Director of Department of Preventive Medicine, Johns Hopkins University School of Medicine

Medical Education in Europe
WILBURT C. DAVISON, M.D., Durham, N. C., Dean, Duke University School of Medicine

Affiliation of Veterans' Hospitals with Medical Schools
PAUL B. MAGNUSON, Washington, D. C., Director of Research and Education, Veterans Administration

Discussion led by C. SIDNEY BURWELL, M.D., Boston, and William S. Middleton, M.D., Madison, Wis.

Address
GEORGE F. LULL, M.D., Chicago, Associate General Manager, American Medical Association, Major General, U. S. Army.

MONDAY AFTERNOON—2:00

RAY LYMAN WILBUR, M.D., *Presiding*

GENERAL AND SPECIALTY PRACTICE

Problems in Specialty Practice
PAUL TITUS, M.D., Pittsburgh, President, Advisory Board for Medical Specialties

The Practice of General Medicine
WILLIAM A. O'BRIEN, M.D., Minneapolis, Director of Postgraduate Education, University of Minnesota Medical School

Discussion led by ALPHONSE M. SCHWITALLA, S. J., St. Louis.

MEDICAL EDUCATION AND RESEARCH

Federal Aid for Medical Research
KENNETH B. TURNER, M.D., New York, Member, Medical Advisory Committee on the Report of Dr. Vannevar Bush to the President

Research in Undergraduate Medical Education
DETLEV W. BRONK, Ph.D., Philadelphia, Director, Eldridge Reeves Johnson Foundation for Medical Physics, University of Pennsylvania School of Medicine

Protection of Animal Experimentation
A. J. CARLSON, M.D., Chicago, Temporary Chairman, Organizing Board of Directors, National Commission for the Protection of Medical Science

Discussion led by EWEN MACEWEN, M.D., Iowa City and JOSEPH C. HINSEY, Ph.D., New York

THE FEDERATION OF STATE MEDICAL BOARDS

MONDAY—6:30

FEDERATION DINNER

The People's Health—A National Asset
HON. WATSON MILLER, Washington, D. C., Administrator, Federal Security Agency.
Room Fourteen

TUESDAY MORNING—9:30

ADAM P. LEIGHTON, M.D., *Presiding*

Presidential Address
ADAM P. LEIGHTON, M.D., Portland, Maine, President, Federation of State Medical Boards

Why Require Graduates of Approved Medical Schools to Pass a Basic Science Board Examination?
H. M. PLATTER, M.D., Columbus, Ohio, Secretary, Ohio State Medical Board

Part III of the National Board Examination—Its Character and Purpose
J. STEWART RODMAN, M.D., Philadelphia, Medical Secretary, National Board of Medical Examiners

Recent Licensure Developments in Massachusetts
H. Q. GALLUPE, M.D., Boston, Secretary, State Board of Registration in Medicine

Licensure by Reciprocity or Interstate Endorsement
ROY B. HARRISON, M.D., New Orleans, Secretary, Louisiana State Board of Medical Examiners

Recent L[illegible] Medical Licensure
Mr. J. [illegible] rector, Bureau of Legal Medicine and [illegible] Association

TUESDAY—12:30

FEDERATION LUNCHEON
Room Nine

TUESDAY AFTERNOON—2:00

ADAM P. LEIGHTON, M.D., *Presiding*

Business Session—Reports of Officers—Reports of Committees—New Business

CENTRAL COUNCIL FOR NURSING EDUCATION

MONDAY, 12:15

LUNCHEON FOR LAY BOARDS OF HOSPITALS AND PUBLIC HEALTH NURSING ORGANIZATIONS

Community Planning for Health
MR. SAMUEL A. GOLDSMITH, Chicago, Chairman of Health Division of Council of Social Agencies of Chicago
Grand Ballroom

Official Notes

DR. LULL APPOINTED ASSOCIATE GENERAL MANAGER

Dr. George F. Lull, formerly deputy Surgeon General, United States Army Medical Corps, has been appointed Associate General Manager of the American Medical Association and began work in his new position on January 1.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Feb 11-12. Dr. Victor Johnson, 535 North Dearborn St., Chicago, Secretary.

Conference of State Secretaries and Editors, Chicago, Feb 8-9. Dr. Olin West, 535 North Dearborn St., Chicago, Secretary.

American Association of Pathologists and Bacteriologists, Chicago, March 8-9. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.

American Orthopsychiatric Association, New York, Feb 14-16. Dr. Nina Ridenour, 1790 Broadway, Room 916, New York 19, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 5-8. Dr. Warren W. Furey, 30 North Michigan Ave., Chicago 2, Secretary.

Southeastern Surgical Congress, Memphis, Tenn., March 11-13. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S. E., Atlanta 3, Georgia, Secretary.

Committee on Scientific Exhibit

MOTION PICTURES AND SLIDE FILMS ON HEALTH

Your Fight Against Infantile Paralysis. 16 mm., sound, motion picture. Running time 15 minutes.

This new motion picture shows the various methods being used in the treatment of the disease and some of the research going on for its prevention. It ends with a plea to continue these efforts. Further information may be obtained from the National Foundation for Infantile Paralysis, Inc., 120 Broadway, New York 5.

Weathering the Storms. Slide film. 35 mm., sound, 17 minutes.

This is a picture for laymen, explaining psychoneurosis, its cause and its prevention. The picture is intended for civilians, emphasizing the fact that psychoneurosis is not a disease peculiar to military personnel. It is suitable for use by medical officers of the Army and Navy.

The film may be obtained on a free loan basis from agents of the Zurich Insurance Companies. Further information may be obtained from the Industrial Welfare Department, Zurich Insurance Companies, 135 South LaSalle Street, Chicago 3.

Medical Legislation

STATE LEGISLATION

Massachusetts

Bills Introduced.—S. 44 proposes to authorize the department of public health to investigate and study the causes of poliomyelitis, commonly called infantile paralysis, and the eradiation of such disease.

S. 45 proposes to authorize all duly registered physicians, on application, to practice in, and have his patients admitted to, any public or semipublic hospital, any hospital supported in whole or in part by contributions from the commonwealth, any city or town, or the public, or any hospital which solicits contributions for its support from the public.

S. 46, to amend the medical practice act, proposes the creation of a board of registration of chiropractors for the regulation, examination and licensing of such practitioners and defines chiropractic as "the science of locating, and removing, by hand only, interference with the transmission or expression of nerve force in the human body, where such interference is indicated or misalinement or subluxations of the vertebral column appear. It excludes operative surgery, prescription or use of drugs or medicine, or the practice of obstetrics, except that the x-ray may be used solely for the purposes of examination."

H. 57, to amend the law relating to patients in institutions under the supervision of the department of mental health, proposes that no restraint in the form of buckles, waist straps, anklets, etc., shall be imposed on any such patient unless applied in the presence of the superintendent, or of the physician or of an assistant physician of the institution, or on his written order, which shall be preserved in the files of the institution for a period of two years.

H. 74, to amend the law relating to bacteriologic laboratories, proposes to authorize the department of public health to grant certificates of approval for laboratory tests on milk, foods, eating utensils, water and sewage in accordance with such rules and regulations as the department may establish.

H. 76, to amend the hospital licensing law, proposes to include thereunder the operation of convalescent homes and nursing homes, defined as "any institution, whether conducted for charity or profit, which is advertised, announced or maintained for the express or implied purpose of caring for three or more persons, not acutely ill, admitted thereto for the purpose of chronic or convalescent care."

H. 78, to amend the law relating to the department of public health, proposes to authorize such department to conduct clinics for the diagnosis and treatment of patients ill with chronic disease.

H. 115 proposes the enactment of a voluntary system for the payment of hospital, surgical operation, sickness and bodily injury and maternity benefits to employees.

H. 117 proposes to punish any person who experiments or operates in any manner whatever on any living dog or cat for any purpose other than the healing or curing of said dog or cat.

H. 230, to amend the medical practice act, proposes to authorize the board of medical examiners to grant certificates of registration, without examination, to such persons as shall furnish with their applications satisfactory proof that they have the qualifications required in Massachusetts to entitle them to be examined and have been licensed or registered on a written examination in another state whose standards, in the opinion of the board, are equivalent to those in Massachusetts. The bill further proposes that no person shall be registered without an examination if he is a graduate of a medical school not approved by the approving authority.

H. 261, to amend the hospital lien law, proposes the creation of a lien in favor of any hospital receiving state aid or any hospital owned, operated or aided by a city or town on the proceeds of any insurance policy issued to the person alleged by the patient to be responsible for the accident.

H. 268, to amend the workmen's compensation law, proposes to authorize an injured employee to be treated by a physician of his own selection, the reasonable cost of such physician's services, including reasonable fees for testimony given at any hearing conducted by the industrial accident board, to be paid by the insurer.

H. 269, to amend the workmen's compensation law, proposes that fees of attorneys and physicians and charges of hospitals shall be paid by the insurer or self insurer.

H. 298, to amend the law regulating the practice of pharmacy, proposes to authorize the board and the commissioner of education to establish standards to be met by colleges of pharmacy and to grant certificates of approval to colleges meeting such standards as well as to revoke any certificate of approval previously issued to any college which lowers its standards below that established by the board and the commissioner.

H. 299, to amend the medical practice act, proposes that all persons who matriculated at the Middlesex University School of Medicine during the month of January 1941 and were duly graduated therefrom on July 24, 1944 and subsequently served as interns shall be eligible for examination and registration in medicine in the state.

Bureau of Information

SUMMARY SHEETS FROM TEXAS

Completed county summary sheets have been received from counties in Texas through Dr. Holman Taylor, secretary, State Medical Association of Texas.

The accompanying table gives data from selected counties in these states. The column giving the number of persons per telephone is used as one index of the economic status of the area.

Texas

County [1]	Principal Cities [2]	Population	Physicians Under 65	Persons per Physician	Persons per Telephone [3]
Bosque		12,030	6	2,005	14
Cooke		23,865	7	3,409	15
	Gainesville	9,651			
Crosby		11,606	2	5,803	57
Fayette		23,711	10	2,371	16
	LaGrange	2,531			
Gray		22,099	10	2,210	11
	Pampa	12,895			
Hidalgo		94,270	39	2,417	32
	McAllen	11,877			
	Edinburg	8,718			
	Mercedes	7,624			
Llano		4,328	2	2,164	7
	Llano	2,658			
Mitchell		11,532	3	3,844	16
	Colorado City	5,213			
Presidia		8,393	3	2,798	21
	Marfa	3,805			
Wichita		72,981	52	1,403	10
	Wichita Falls	45,112			
	Electra	5,588			
	Burkburnett	2,814			

1. Bureau of Census, estimated population 1943.
2. Bureau of Census, population 1940.
3. Based on 1940 figures, American Telephone and Telegraph Company.

Many physicians over 65 years of age are carrying on large practices and are doing much to maintain the health of communities. They are not included in computing physician population ratios, however, as the future needs of the communities will be largely dependent on younger physicians.

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the state and county secretaries and are then available to inquiring medical officers. Frequent reports from state and county medical societies about needs of communities for doctors will help maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Thomas Morgan Dies.—Thomas H. Morgan, Ph.D., professor emeritus of biology, California Institute of Technology, and in 1933 winner of the Nobel Prize for his research on heredity, died in Huntington Memorial Hospital, Pasadena, December 4, aged 79. Dr. Morgan won the Nobel Prize in medicine for his "discoveries relating to the heredity function of chromosomes."

The Reginald Knight Smith Lecture.—Dr. Max Pinner, New York, clinical professor of medicine, Columbia University College of Physicians and Surgeons, New York, will deliver the second Dr. Reginald Knight Smith Lecture on January 24 at the Mount Zion Hospital, San Francisco, sponsor of the lecture. The subject will be "Modern Trends in the Treatment of Pulmonary Tuberculosis."

DELAWARE

Personal.—Dr. Howard L. Reed has been appointed assistant medical director of the Hercules Powder Company, Dr. Lemuel C. McGee, Wilmington, Hercules medical director, announced on January 3. Dr. Reed has been medical director of the Hercules operated Sunflower Ordnance Works in Kansas for the past two years. Prior to that he was medical director of the Hercules operated Badger Ordnance Works in Wisconsin. Dr. Reed graduated at Duke University School of Medicine, Durham, N. C., in 1936.

ILLINOIS

County Health Department Operating.—The Cook County Department of Health is now functioning in accordance with action taken by the board of commissioners on Dec. 10, 1945. Since July 1, 1940 the public health unit had been operating within the department of public welfare. Under the new setup Dr. Edward A. Piszczek, Chicago, who had been director of the old unit, will continue in charge with the title of chief medical officer. The county organization now has the authority to develop its own regulations and to coordinate more closely the health activities in Chicago, Evanston, Winnetka and Kenilworth, which have their own units.

Chicago

Funds Released for Medical Center.—Governor Dwight H. Green recently released $641,000 to acquire property for the West Side Medical Center. The sum is part of $1,100,000 designated for the center and included in the state's postwar public works program.

Chemical Factors in Inflammation.—The School of Medicine of the University of Chicago sponsored a public lecture December 7 on "The Role of Chemical Factors in Inflammation." The lecturer was Dr. Valy Menkin, assistant professor of pathology, Duke University School of Medicine, Durham, N. C.

Health Service to Survey Chicago.—Dr. Frank V. Meriwether, director, district of the U. S. Public Health Service, announced December 19 that his office will begin a survey of Chicago health facilities on February 1. The study was requested by the Chicago Medical Society, the Institute of Medicine of Chicago and the health division of the Chicago Council of Social Agencies. Brig. Gen. James Thompson, U. S. Public Health Service, now stationed in Japan, will direct the project. It is estimated that from eight months to a year will be required to complete the work.

Personal.—Dr. Max Thorek recently received the civilian decoration of the Peruvian government, the "Order of the Sun." The presentation was made by Dr. Humberto Fernandez-Davilla, minister counselor of the embassy in Washington, in recognition of Dr. Thorek's contributions to surgical science.——Dr. Edward D. Allen has been appointed acting head of the department of obstetrics and gynecology at Presbyterian Hospital to succeed Dr. N. Sproat Heaney, who resigned and moved to Beverly Hills, Calif., where he has entered practice. Dr. Heaney became acting chairman of the department in 1921 and chairman in 1924.——Jon M. Jonkel has resigned as director of the department of public relations, American Hospital Association, effective January 5, to establish an organization specializing in the public relations problems confronting hospitals.

KENTUCKY

Woman Physician Honored.—Friends of Dr. Alice N. Pickett, Louisville, professor and executive of the division of obstetrics, have established the Alice Pickett Fund for Obstetrical Gynecology. The fund was set up to honor Dr. Pickett, who has been at the University of Louisville School of Medicine for many years, and to assist the school of medicine and hospital to obtain a full time head of the department of obstetrics and gynecology, to buy equipment and to provide funds for research.

Campaign Opened to Develop Rural Physician Program.—The plan of the Kentucky State Medical Association to set up a revolving fund of $50,000 to $75,000, to be designated a scholarship fund for medical students who agree to practice in country districts after graduation, was launched December 12 at a dinner. Dr. Carl C. Howard, Glasgow, author of the program, was unable to attend the meeting because of illness. Dr. Gaithel L. Simpson, Greenville, presided instead. The tentative plans for the scholarships call for the revolving fund. Ten students would be assisted annually on an estimated tuition of $550 and be required to practice in rural areas and repay the principal within ten years at nominal interest. The action to sponsor this program was planned at the recent annual meeting of the Kentucky State Medical Association (THE JOURNAL, Oct. 27, 1945, p. 642).

MASSACHUSETTS

Reginald Smithwick Named Professor at Boston University.—Dr. Reginald H. Smithwick, instructor in surgery at Harvard Medical School, Boston, has been appointed professor and chairman of the department of surgery at Boston University School of Medicine and surgeon in chief of the Massachusetts Memorial Hospitals. In his new position Dr. Smithwick, who graduated at Harvard in 1925, will continue and extend his investigations on the surgical treatment of hypertension and peripheral vascular disease.

Tufts Medical Alumni Lecture.—The annual Tufts Medical Alumni Lecture will be given on February 20 at the Tufts College Medical School, Boston, by Dr. Winthrop Adams, manager of the Veterans Administration Facility at Bedford. His subject will deal with the possibilities of a medical career with the Veterans Administration. Dr. Adams was recently appointed deputy surgeon general of one of the thirteen U. S. districts formed under the reorganization plan of the Veterans Administration. The district which Dr. Adams will head will have its center in Boston and will comprise seven hospitals, five regional offices and three hospitals yet unbuilt.

Fellowship for Advanced Research in Genetics or Mental Health.—Radcliffe College, Cambridge, invites application for the Helen Putnam Fellowship for Advanced Research in the general field of genetics or of mental health. The fellowship, carrying a stipend of $2,000 and covering a period of eleven months from October 1, is open to mature women scholars who have gained their doctorate or who possess similar qualifications and who have research in progress. Applications for the award must be submitted to Radcliffe College not later than April 1. All normal laboratory facilities will be provided to the winner of the Putnam Fellowship, whose appointment will be announced about May 1 by the committee on award.

Brigadier General Simmons New Dean of School of Public Health.—Brig. Gen. James S. Simmons, U. S. Army, chief, preventive medicine service, Office of the Surgeon General, has been appointed dean of the Harvard University School of Public Health, it was announced January 10. He is expected to take over the position July 1. The Rockefeller Foundation has granted $1,000,000 for expenses of the school of public health from July 1, 1946 to June 30, 1956, and Harvard University has set aside an additional sum of $750,000 as an endowment for the school to supplement the present endowment fund. In a reorganization intended to make this one of the foremost research and teaching institutions in the world, the school of public health will have coequal status in the university with the medical school and other professional divisions. In addition to its present marble building at 55 Shattuck Street, Boston, the school of public health will occupy Collis P. Huntington Memorial Hospital, which was used before the war for cancer and tumor research and during the war by the government for secret experiments. Acquisition of the hospital, which is to be remodeled, will give the school an additional 40,000 square feet of floor space. Founded in 1922 with the aid of a Rockefeller Foundation grant now known as the Henry P. Walcott Endowment Fund, the Harvard school of public health pioneered in special departments such as industrial hygiene and child health. Dr. Edward G. Huber is acting dean of the school of public health. Brigadier General Simmons, born in Newton, N. C., June 7, 1890, graduated at the University of Pennsylvania School of Medicine in 1915 and at the Army Medical School in 1917. He received a Ph.D. degree from George Washington University Medical School in 1934 and the degree of doctor of public health from the Harvard school of public health in 1939.

MICHIGAN

Personal.—Dr. Edward E. Dart, Chicago, recently physician in charge at Chrysler's Dodge plant in Chicago, has become chief of Chrysler's Industrial Hygiene Laboratory, Detroit, succeeding Dr. Lewis L. Kline.——Dr. Hugh L. Dill, Detroit, recently declined to be a candidate to succeed himself in the office of mayor of Grosse Pointe City. Dr. Dill had been mayor since February 1944, when the previous mayor died. He has served the city for eleven years as councilman and mayor.

Campaign Against Drug Store Prescribing.—The Michigan State Board of Health, in cooperation with the county prosecutors, the police and sheriffs' officers, is conducting a campaign to stamp out illegal medical practice by pharmacists, newspapers reported December 22. In a Detroit survey it was revealed that, in a third of 756 drug stores canvassed, pharmacists were willing to diagnose and prescribe remedies for venereal disease. The outstate survey of 242 stores showed that 40 per cent would perform similar service.

Secretaries' Conference.—The annual County Secretaries Conference of the Michigan State Medical Society will be held at the Wardell-Sheraton Hotel, Detroit, January 20. Among the speakers will be:

Dr. Robert L. Novy, Detroit, Progress Report on Michigan Medical Service.
Col. James C. Harding, M. C., Washington, Veterans Administration Plan for Michigan.
Dr. Louis F. Foster, Bay City, Uniform Fee Schedule for Governmental Agencies.
Dr. Earl I. Carr, Lansing, Michigan Foundation for Medical and Health Education.
Dr. George F. Lull, Chicago, Postgraduate Medical Education.
Dr. Edward J. McCormick, Toledo, Ohio, Medical Public Relations.

MISSOURI

The Terry Lecture.—Dr. Loyal Davis, professor of surgery, Northwestern University Medical School, Chicago, gave the annual Robert J. Terry Lecture before the St. Louis Medical Society, December 18. His subject was "Experimental and Clinical Investigations on Surgery of Peripheral Nerve Injuries."

Society Honors Laymen and Physicians.—Three laymen were honored recently by the Jackson County Medical Society for their interest in public health. A certificate of award went to each of the three men: to Mr. Homer H. Berger for his interest in the medical society and the development of the Blue Cross Hospital Service, of which he is the legal counsel, to Mr. Arthur B. Church, president of KMBC radio station for maintaining on the radio for over four years the program "health and happiness," presented each Sunday evening in cooperation with the society, and to Mr. Forrest F. Dodd, president of the Blue Cross Hospital Service, for the successful progress of that service. The Lay Honor Award originated in 1944, when the first award was presented to Mrs. Ruth A. Hirsch in tribute to her work in the development of the Jackson County Health Forum (THE JOURNAL, May 6, 1944, p. 73). The society also presented merit awards with the gold key of the society to Drs. Ambrose E. Eubank for his devoted interest and service to the society, to James R. McVay for service to the profession through his interest in medical education and legislation, and to Edward H. Skinner, all of Kansas City, for his direction and development of the society's library. Dr. Eubank and Dr. Skinner were not present to receive the awards, nor were Mr. Church and Mr. Dodds.

NEW HAMPSHIRE

University Physician Appointed.—On January 3 Major Walter E. Batchelder, who is on terminal leave from the army, began his activities as newly appointed physician and director of the health service of the University of New Hampshire, effective January 3. Dr. Batchelder graduated at the Boston University School of Medicine in 1939.

NEW YORK

Paul Brooks Retires.—Dr. Paul B. Brooks, Albany, deputy state commissioner of health, retired January 1 after thirty years of service on the staff of the state department of health. Dr. Brooks joined the state department of health in 1915, subsequently serving as district sanitary supervisor, acting director of the division of communicable disease and assistant director of laboratories and research. In 1923 he was named deputy commissioner. He has been secretary of the Chenango County Medical Society and the International Association of Milk Sanitarians, serving also as president of the latter.

Hospital and Medical School Cooperate in New Program.—The Genesee Hospital and the University of Rochester School of Medicine and Dentistry have agreed on a close working relationship, each institution to maintain its complete operating and administrative independence and the facilities of the two hospitals to be available to the teaching staff of each. A statement points out that though this is not a formal agreement the leadership in both institutions assumes the responsibility for the success of the project, which is patterned on the "very successful relationship that exists between the Massachusetts General Hospital and Harvard Medical School." To achieve a successful arrangement, the following recommendations were made:

That all directors of departments of the Genesee Hospital shall be appointed in the customary manner, that is, by the hospital's board of governors, with the advice of the advisory board of the school of medicine and dentistry.

The nonteaching members of the staff of all grades and in all departments of the Genesee Hospital shall be appointed in the customary manner by the board of governors on the recommendation of the director of each department and of the medical board.

That all the teaching members of the staff of all grades and in all departments of the Genesee Hospital shall be appointed in the customary manner by the board of governors on the recommendation of the director of each department and of the medical board, with the advice of the advisory board of the school of medicine and dentistry.

New York City

Meeting on Diabetes.—The New York Diabetes Association, Inc., will hold an open meeting at the New York Academy of Medicine, January 26. Dr. Charles H. Best, Toronto, Canada, will discuss "A Quarter of a Century in Medical Research" and "Factors Affecting Fat Transport in the Animal Body." Dr. Reginald E. Haist, Toronto, will talk on "Carbohydrate Metabolism in Traumatic Shock."

Hospital Provides Office for Returned Staff Members.—Sydenham Hospital is arranging to make available a fully equipped office for the use of its staff doctors while they are getting reestablished in practice on their return from military service. The hospital will provide the space, and the doctors who did not go to war will underwrite the equipment of the office and the provision of a nurse-secretary while the returning physicians find permanent quarters, and as the returning doctors become able to contribute to the secretarial cost they will be expected to do so. The hospital's dental clinic will be made available in a similar way to staff dentists back from war duties. The clinic is already fully equipped, according to the New York *Times*.

Walter Reed Chosen for Hall of Fame.—Dr. Walter Reed, noted for his work on yellow fever, was the only physician elected to the Hall of Fame for Great Americans on the campus of New York University recently. The physician was one of four famous men who were chosen by a vote of 93 distinguished men and women who comprised the "College of Electors" from a field of 130 candidates nominated by the public. The election brings to 77 the number of historical figures chosen for the honor of a place in the Hall of Fame since it was founded in 1900 by the late Chancellor Henry Mitchell MacCracken. Dr. Reed is the first member of the medical profession to be chosen because of his contribution to medical knowledge and the first alumnus of the New University College of Medicine to receive this distinction. He died in 1902. The recent election was the tenth quinquennial election. In addition to Dr. Reed, who was elected, seven other physicians were named as nominees:

William Beaumont (1785-1853), discoverer of the physiology of digestion.
William T. H. Bellamy (1844-1911), physician, surgeon.
Elizabeth Blackwell (1821-1910), first American woman medical graduate.
Reginald Heber Fitz (1843-1913), discoverer of appendicitis.
William Crawford Gorgas (1854-1920), noted for work on yellow fever.
Ephraim McDowell (1771-1830), distinguished surgeon.
Benjamin Rush (1745-1813), physician and signer of the Declaration of Independence.

PENNSYLVANIA

Pittsburgh

Nu Sigma Nu Lecture.—Dr. John R. Paul, professor of preventive medicine, Yale University School of Medicine, New Haven, will give the first lecture in a new lectureship recently established by the Nu Sigma Nu Medical Fraternity, University of Pittsburgh School of Medicine. Dr. Paul will speak January 23 on "Infectious Hepatitis."

VIRGINIA

New Professor of Pharmacology.—Dr. Chalmers L. Gemmill, associate professor of physiology, Johns Hopkins University School of Medicine, Baltimore, and for the past four years on leave of absence as commander in the Medical Corps, U.S.N.R., in charge of aviation medical research at the Naval Air Station, Pensacola, Fla., has been appointed professor of pharmacology at the University of Virginia Department of Medicine, Charlottesville, succeeding the late Dr. James A. Waddell.

Changes in Health Officers.—Dr. John G. McNiel, Bristol, has been named health officer of the Southside Health District, effective October 26. Dr. Willard W. Griggs, Newport News, has been named health officer of the Page-Warren-Shenandoah Health District, effective November 1. Dr. John C. Sleet has resigned as health commissioner of Norfolk. Dr. Albert L. Chapman, Wrightstown, N. J., U. S. Public Health Service, has been assigned to succeed Dr. Henry B. Hoff as assistant health commissioner. Dr. Hoff plans to enter private practice in Pennsylvania. In his new position Dr. Chapman will be eligible to serve as acting health commissioner on Dr. Sleet's resignation. Dr. James M. Suter, Bristol, has returned to service with the Virginia Department of Health as health officer of the Smyth-Washington-Bristol Health District, effective December 6. Dr. Frederick C. Heath, Laureldale, Pa., has been appointed health officer of the Giles-Montgomery-Radford Health District, with headquarters at Christiansburg, effective January 1.

WEST VIRGINIA

Uniform Procedures for Aid in Tuberculosis.—A change in the method of determining eligibility for state aid to tuberculous patients requiring sanatorium care and pneumothorax refills has been announced by Dr. Robert L. Smith, Charleston, acting director of the bureau of tuberculosis control. The new procedure, which will permit a more equitable consideration of cases and which will systematize fiscal handling, is in line with the provisions of a cooperative arrangement recently made by Dr. John E. Offner, Weston, state health commissioner, with the department of public assistance, which provides for the latter to supply social and financial information concerning the families of patients. Details of the new program will be handled by Mr. Charles W. Rogers, formerly of New Martinsville, who will have headquarters in the bureau of tuberculosis control in Charleston. Mr. Rogers, who is a trained social worker, will serve in a liaison capacity between the bureau, local health departments, offices of the DPA and tuberculosis sanatoriums. Physicians who have tuberculous patients needing sanatorium care, the cost of which they are unable to meet themselves, will fill out and sign an application for admission to a state sanatorium. This application may be signed by a county health officer if a physician has not been in charge of the case. The application is to be presented to the local DPA by the patient or by a responsible representative. An investigator for the department will then complete a certified report concerning family income and expenses and will forward the report to the bureau of tuberculosis control, which will determine eligibility for state aid. No delay will be occasioned when the families of patients are already known to DPA workers. Persons eligible for state aid will be certified to a sanatorium, and the patient will be advised when to report for hospitalization. A person found ineligible for a state subsidized bed will have his application returned, and he may then submit it directly to the sanatorium by agreeing to pay the required fee of $1 a day per patient. When a state aid patient is discharged from the sanatorium with the approval of the medical staff, recommended pneumothorax refills may be paid for out of state funds. The patient himself selects a physician who is qualified under the standards adopted by the public health council, and a pneumothorax referral is forwarded to the bureau of tuberculosis control, which in turn transmits an authorization for treatment to the doctor. Pneumothorax refills are not paid for when a patient leaves a sanatorium without official permission. Patients who are already paying for sanatorium treatment and care may apply for state aid through a county health officer if he later becomes unable to continue such payments, and this application is processed under the same method provided for consideration of original applications for state aid.

GENERAL

Society News.—The Central States Dermatological Society will meet at the Harper Hospital in Detroit, April 27. Dr. Clarence E. Reyner, Henry Ford Hospital, Detroit, is secretary.——The next annual meeting of the American Urological Association will be held at the Netherland Plaza Hotel, Cincinnati, July 22-26.——The Medical Library Association will hold its annual meeting at Yale University, New Haven, Conn., March 25-27.

Clinical Fellowships in Medicine Nearly Exhausted.—The clinical fellowships in medicine offered by the American College of Physicians to provide further training for returning veteran medical officers are nearly exhausted. Because of the large number of applications on hand and pending, no further applications will be accepted by the Office of the Educational Director, 4200 Pine Street, Philadelphia 4, after February 1.

Committee on Deaf-Blind.—Announcement was made recently of the formation of the Helen Keller Committee on the Deaf-Blind as a department of the American Foundation for the Blind, 15 West 16th Street, New York 11. The objectives of the new committee are to:

Improve educational methods for the deaf-blind on an individual basis to provide greater self resourcefulness, thus compensating for limited contacts with others.

Find a shorter and more rapid manual language to speed communication with family and friends.

Obtain greater vocational opportunities for the deaf-blind in workshops for the blind and in private industry.

Increase the social relationships of the deaf-blind by developing special activities for them and by devising ways to permit them to participate in usual recreations.

Special Society Elections.—Dr. Robert V. Seliger, Baltimore, was reelected president of the Medical Correctional Association at its annual meeting in New York, November 15-16. Other officers are Dr. Frank J. Curran, New York, and Dr. Michael J. Pescor, Springfield, Mo., vice presidents, and Robert M. Lindner, Ph.D., Baltimore, secretary-treasurer. The Medical Correctional Association is an affiliate of the American Prison Association.——At the annual meeting of the American Society of Tropical Medicine in Cincinnati, November 13-15, Brig. Gen. James S. Simmons, Washington, D. C., was inducted into the presidency, Dr. Edward I. Salisbury, New York, was chosen president-elect, Dr. Joseph S. D'Antoni, New Orleans, vice president, and Dr. Norman H. Topping, Bethesda, Md., secretary-treasurer.

Orthopedic Surgery Meeting.—The thirteenth annual meeting of the American Academy of Orthopaedic Surgeons will be held at the Palmer House, Chicago, January 19-23, under the presidency of Dr. Eugene B. Mumford, Indianapolis. Among the speakers will be:

Drs. Alfred W. Adson, Henry H. Young and Ralph K. Ghormley, all of Rochester, Minn., Combined Neurectomy and Bone Graft in Spastic *Torticollis*.
Dr. Joseph A. Freiberg, Cincinnati, Arthrodesis of the Hip, Brittain type.
Dr. Edward L. Compere, Chicago, Treatment of Congenital Dislocation of the Hip.
Capt. Samuel B. Fowler, M. C., Mobilization of the Metacarpophalangeal Joints—Arthroplasty and Capsulotomy.
Major James V. Luck, M. C., Psychologic Problems Observed in Military Orthopedic Surgery.
Dr. Jean Verbrugge, Antwerp, Belgium, Factors Influencing Bone Repair in Open Reductions of Fractures.
Dr. George O. Eaton, Baltimore, Overseas Treatment of Compound Fractures of the Long Bones.
Lieut. Col. Harry C. Blair, M. C., and Major Harry D. Morris, M. C., Conservation of Short Amputation Stumps by Utilization of Tendon Section.
Dr. Duncan C. McKeever, Houston, Texas, Cellophane in Reconstructive Orthopedic Surgery.

Grants for Research in Endocrinology.—The committee on research in endocrinology, National Research Council, wishes to announce that requests for grants-in-aid during the fiscal period from July 1, 1946 to June 30, 1947 will be received until Feb. 28, 1946. Application blanks may be obtained by addressing the secretary, Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, Washington 25. In addition to a statement of the problem and research plan or program, the committee desires information regarding the proposed method of attack, the institutional support of the investigation and the uses to be made of the sum requested. No part of any grant may be used by the recipient institution for administrative expenses. The committee makes grants in aid of research in the general field of experimental and clinical endocrinology. However, applications for support of research in the problems of sex in the narrower sense cannot be given favorable consideration, and investigators seeking support in this field should direct their proposals to the committee for research in problems of sex of the National Research Council. The committee on research in endocrinology, however, will continue to give consideration to the support of studies of the effect of sex hormones on nonsexual functions, e. g. on general metabolism and on the metabolism of steroid hormones.

College of Surgeons Resumes Sectional Meetings.—The American College of Surgeons announces the resumption in 1946 of its sectional meetings, which during the war were replaced by one day war sessions. Ten two day meetings are planned, to begin in Minneapolis, with headquarters at the Radisson Hotel, on January 28-29. Other meetings will be:

Hotel Jefferson, St. Louis, January 31-February 1.
Tutwiler Hotel, Birmingham, February 8-9.
William Penn Hotel, Pittsburgh, March 11-12.
Statler Hotel, Boston, March 18-19.
Mount Royal Hotel, Montreal, March 22-23.
Statler Hotel, Detroit, March 26-27.
Utah Hotel, Salt Lake City, April 8-9.
Multnomah Hotel, Portland, Ore., April 12-13.
Biltmore Hotel, Los Angeles, April 17-18.

The medical profession at large, medical students and hospital executives are invited to join with the fellows of the college in these meetings. Separate meetings are planned each morning and afternoon for hospital personnel, with joint luncheon sessions on both days and a dinner meeting on the first evening. The programs for the medical profession begin at 8:30 each morning with the showing of medical motion pictures followed by scientific sessions. Scientific sessions will also be held each afternoon. The dinner on the first evening will be followed by a forum on graduate training in surgery. Among the subjects scheduled for discussion at the meetings for the medical profession are the treatment of infection by chemotherapy and the antibiotics; injuries to the bile ducts; preoperative and postoperative supportive treatment; treatment of open wounds; treatment of osteomyelitis; management of advanced cancer; the care of the veteran, and the reconversion period in the practice of medicine. The hospital conferences will be devoted to discussion of high standards for postwar hospitals, approached from the standpoint of administration, professional services and care of different types of patients. Headquarters of the American College of Surgeons are in Chicago. Dr. Irvin Abell, Louisville, is chairman of the board of regents; Dr. William E. Gallie, Toronto, is president, and Dr. Malcolm T. MacEachern and Dr. Bowman C. Crowell, both of Chicago, are associate directors.

HAWAII

Varied Nationalities Represented in Society.—Mrs. Edith C. Bennett, executive secretary of the Hawaii Territorial Medical Association, on December 12 reported that within its membership of 251 the Honolulu County Medical Society has 67 doctors of Japanese, 41 of Chinese, 5 of Korean, 1 of Hawaiian and 137 of European descent. Doctors representing this diversity of origin not only are members but occupy important official positions. The chairman of the program committee, for instance, is Dr. Samuel L. Yee, Honolulu, of Chinese extraction. The man in charge of public relations is Dr. Homer M. Izumi Kula, of Japanese extraction. Joseph Lam, of Chinese extraction, is a member of the board of governors.

Plantation Physicians Hold Meeting.—New officers of the Territorial Association of Plantation Physicians, elected during a meeting in Honolulu November 9-11, are Dr. Paul H. Liljestrand, Aiea, Oahu, president, Dr. William D. Balfour, Wailuku, Maui, vice president, and Dr. Marvin A. Brennecke, Waimea, Kauai, secretary-treasurer. Among the speakers were:

Major Orlando S. Koepsel, M. C., Corpus Christi, Texas, *Proper Handling of Incised Wounds, Lacerations and Cut Tendons.*
Major Norris L. [illegible] [illegible]iti, *Some Unknown Factors in Producing* [illegible]
Dr. Brennecke, [illegible] *Compared with the Kaiser Hospitals.*
Dr. Alvin C. Dougan, Honolulu, *New Developments in the Field of Mechanics and Electronics by Plantation Doctors.*

Medical Society Donates Textbooks to Philippine University.—In a move to supply badly needed medical textbooks to the University of the Philippines College of Medicine, Manila, members of the Honolulu County Medical Society have donated nearly a thousand volumes from their personal libraries, according to John D. Williams, navy correspondent. The plea for medical books and periodicals was raised by Lieut. Comdr. George F. Hoppe of Squadron VR-11, Naval Air Transport Service, who has been voluntarily gathering books of every description for the Philippine educational system. In his one man campaign to arouse interest Lieutenant Commander Hoppe, a former Minnesota school superintendent, suggested the need of medical textbooks to Dr. Morton E. Berk, Honolulu. Members of the Honolulu County Medical Society were invited to donate any of their unused textbooks or periodicals. Lieutenant Commander Hoppe gathered the medical volumes and dispatched them to the Medical School of the University of the Philippines aboard NATS planes not fully loaded for flight.

PUERTO RICO

Proposed Malaria Control.—The Department of Health of Puerto Rico will carry out a malaria control program during the fiscal year 1945-1946 costing $435,000, according to Act 323 of 1945 passed by the Insular Legislature. The island has been divided into five districts for the purpose of this malaria control program. Home treatment of malaria cases will be performed by sixty public health aids in these districts. The appropriation for this project is $77,600. Control of malaria by means of larvicides and drainage will be continued at San Juan, Santurce, Rio Piedras, Arecibo, Fajardo, Ponce, Villalva, Juan Diaz, Santa Isabel, Salinas, Guaynabo, Arroyo and Patillas. Plants for the construction of drainage pipe and warehouses will be constructed at Ponce, Salinas, Santa Isabel, Juan Diaz, Villalva and Guayama. The utilization of DDT as a residual insecticide will be carried out on the rural area of Santa Isabel, with cooperation of the U. S. Public Health Office. One principal engineer and one entomologist will supervise the drainage projects at Santa Isabel and Ponce. The largest of these projects is the one to be established at Ponce, second largest city on the island, with an appropriation of $103,900.

Government Services

Grants-In-Aid Recommended by Cancer Council

Eight federal grants-in-aid totaling $42,040.94 to further the study of cancer have been recommended by the National Advisory Cancer Council. The two largest grants, $10,000 each, will go to Washington University School of Medicine, St. Louis, for a study of the effect of radioactive phosphorus on leukemia, polycythemia vera and various malignant diseases, and to Memorial Hospital for the Treatment of Cancer and Allied Diseases in New York City for metabolic studies in patients with gastric cancer. Other grants will include $4,700 to the University of Minnesota Medical School, Minneapolis, for a study directed at identifying "precursor groups" of patients in whom cancer of the stomach is developing; $5,000 to Yale University School of Medicine, New Haven, for a study of steroids and enzymes in cancer; $3,600 to the University of Southern California School of Medicine at Los Angeles for a study of chemical characterization of split protein products from the blood of cancer patients; $2,640.94 to Jeanes Hospital in Philadelphia for a study of variations of the Golgi apparatus in human neoplastic diseases; $1,100 to Meharry Medical College, Nashville, for a continuation of investigations and follow-up work at the George W. Hubbard Hospital, and $5,000 to Syracuse University College of Medicine for chemotherapeutic studies in cancer. The National Advisory Cancer Council was created by Congress to advise the Surgeon General of the Public Health Service on all phases of cancer. One of its duties is to review and make recommendations on applications from institutions and individuals for grants-in-aid for cancer research. Applications for grants were few in number during the war, but it is expected that they will increase rapidly as scientists are released from the armed forces and from research projects connected with the war effort. Members of the National Advisory Cancer Council are Dr. James B. Murphy, director of cancer research, Rockefeller Institute for Medical Research, New York; A. Baird Hastings, Ph.D., professor of biologic chemistry, Harvard University; Dr. George M. Smith, Pine Orchard, Conn., director, Anna Fuller Fund, Yale University Medical School; Dr. Sherwood Moore, director, Edward Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis; Dr. Frank E. Adair, New York, president of the American Cancer Society and executive officer of Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, and Dr. Andrew C. Ivy, professor of physiology, Northwestern University Medical School, Chicago.

Deaths

Frederick Cook Warnshuis ⊕ for twelve years speaker of the House of Delegates of the American Medical Association, was found dead January 7 at his home in Windsor, Ontario, aged 65.

Dr. Warnshuis was born in Alton, Iowa, June 16, 1880. He graduated at Hope College, Holland, Mich., and took his degree at the Grand Rapids Medical College in 1902. Dr. Warnshuis had served as president and secretary of the Kent County Medical Society and as secretary of the Michigan state board of medical registration. He was named secretary of the Michigan State Medical Society in 1913, becoming editor of its journal a few years later. In 1934 he resigned both positions to join the California Medical Association as secretary-treasurer and director of public relations. In 1938 he became president of the newly organized American Medico-Legal Association and editor in chief of its journal, with headquarters in Boston. In 1941 he went to the American Consulate in Windsor as acting assistant surgeon, U. S. Public Health Service.

His service with the American Medical Association included membership in the House of Delegates in 1913-1914, 1916, 1918 and from 1920 to 1934. He was Vice Speaker of the House from 1920 to 1922 and Speaker from 1922 to 1934.

During World War I, Dr. Warnshuis was chief and later commanding officer of the Surgical Service, Base Hospital number 99, American Expeditionary Forces.

Fred Gordon Johnson ⊕ Iron River, Wis.; Rush Medical College, Chicago, 1900; born in Oregon, Wis., June 30, 1872; an Affiliate Fellow of the American Medical Association; life member of the State Medical Society of Wisconsin; twice president of the Ashland-Bayfield-Iron Counties Medical Society; served as president of the district medical society, nine years a councilor of the state society, seven years a preceptor of the University of Wisconsin Medical School and a collaborator in establishing and conducting the first tuberculosis sanatorium in Wisconsin; in 1939 was presented with the fifteenth annual Council Award of the State Medical Society of Wisconsin for outstanding work and devotion to duty; died in St. Francis Hospital Superior, September 2, aged 73, of intestinal obstruction.

Joseph Lloyd Warne ⊕ Pottsville, Pa.; Jefferson Medical College of Philadelphia, 1908; born in Nanticoke, Pa., on April 18, 1885; first vice president of the Medical Society of the State of Pennsylvania; fellow of the American College of Surgeons; medical director, founder and owner of the Lemos B. Warne Hospital, which he established in 1932, presenting it to the community on Feb. 1, 1945 as a memorial to his wife; awarded a certificate of meritorious award by Governor Edward Martin in recognition of services to his community; at one time chief surgeon at the Pottsville Hospital; president of the Pottsville Industries, Inc.; member and past president of the chamber of commerce; died October 8, aged 60, of coronary occlusion.

Renos Harlan Richards, Patricksburg, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1903; born Sept. 8, 1876; member of the American Medical Association; member of the state house of representatives; served as president of the Owen County Medical Society and as county coroner and treasurer of Owen County; first lieutenant, medical corps, Indiana National Guard, 1910-1915; captain in the medical corps on the Mexican border, 1916-1917; major in the medical corps, American Expeditionary Forces, in France during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; died in the Robert W. Long Hospital, Indianapolis, September 9, aged 69, of coronary occlusion.

Howard Allison McKnight ⊕ Springfield, Ohio; University of Pennsylvania School of Medicine, Philadelphia, 1910; born in Philadelphia, Dec. 31, [illegible]; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; past president of the Clark County Medical Society; served during World War I; at one time on the faculty of the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, and associate professor of surgery at the Woman's Medical College of Pennsylvania, Philadelphia; on the staff of the Springfield City Hospital, where he died October 7, aged 60, of lymphosarcoma of the retroperitoneal glands.

Leonidas M. Stokes ⊕ Walterboro, S. C.; Medical College of the State of South Carolina, Charleston, 1906; born in 1879; past president and vice president of the South Carolina Medical Association; served as president of the Colleton County Medical Society and as a member of the board of medical examiners; formerly medical director of the Charles Es'Dorn Hospital; presented with a silver service in 1939 by the alumni association of the Medical College of the State of South Carolina in recognition of his services in the securing of new buildings for the medical college, which he served as a member of the board of trustees; died September 23, aged 66, of polycythemia vera.

William Hopton Smith ⊕ Goldsboro, N. C.; University of Pennsylvania Department of Medicine, Philadelphia, 1906; born in Goldsboro, N. C.; May 29, 1882; served as president of the state board of medical examiners; served as president and director of the North Carolina Tuberculosis Association; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; vice president of the Medical Society of North Carolina, of which he had been an honorary member; member of the Southern Medical Association; on the staff of the Goldsboro Hospital; died September 29, aged 63, of relapsing virus pneumonia.

Charles Wilson Mills ⊕ Tucson, Ariz.; Johns Hopkins University School of Medicine, Baltimore, 1908; born in South Williamstown, Mass., September 1, 1879; specialist certified by the American Board of Internal Medicine; member of the American College of Chest Physicians and the American Clinical and Climatological Association; fellow of the American College of Physicians; chief of visiting staff, Desert Sanatorium and Institute of Research; member of the courtesy staff, St. Mary's Hospital and Sanatorium; chairman, medical advisory board, Arizona Selective Service; died September 29, aged 66, of coronary occlusion.

Robert George McAliley ⊕ Atlanta, Ga.; Johns Hopkins University School of Medicine, Baltimore, 1912; associate professor of pediatrics at the Emory University School of Medicine; specialist certified by the American Board of Pediatrics, Inc.; served during World War I; on the staffs of the Emory University, Grady and Crawford Long Memorial hospitals; joint author of "Diseases of the Respiratory System in Infants and Children" (Clinical Pediatrics); died in the Walter Reed General Hospital, Washington D. C., September 15, aged 66, of bacterial endocarditis.

Norman Barkan, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1945; intern at the Mount Sinai Hospital, where he died September 28, aged 23.

Wallace Linn Brittain ⊕ Conway, Ark.; University of Arkansas School of Medicine, Little Rock, 1928; chief of staff at the Conway Memorial Hospital; died September 4, aged 41.

William Edgar Buck, Randolph, Mass.; Medical School of Maine, Portland, 1914; member of the American Medical Association; died in the Milton (Mass.) Hospital September 15, aged 58.

Otto Charles Christmann, Seattle; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; member of the American Medical Association; secretary-treasurer of the Seattle Academy of Surgery; part time epidemiologist in the venereal disease division of the city health department during World War II; served on the staffs of the Columbus, Doctors and Harborview County hospitals; died December 9, aged 63, of coronary disease.

Roy Oscar Cooley ⊕ West Palm Beach, Fla.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1909; past president of the Palm Beach County Medical Society; served during World War I; served as chief of staff of the Good Samaritan Hospital, as chairman of the Palm Beach County Chapter of the American Red Cross and as president of the Rotary Club; died in a hospital at Asheville, N. C., October 3, aged 59, of cerebral hemorrhage.

Arthur Howard Davison, Milton, Mass.; Harvard Medical School, Boston, 1902; member of the American Medical Association; served on the staff of the Milton Hospital; medical director of the Boston Mutual Life Insurance Company and president of the Codman Cooperative Bank of Dorchester; died in the New England Baptist Hospital Boston September 26, aged 71, of carcinoma of the stomach.

Chester Hyman Fairchild, Woodland, Calif.; Cooper Medical College, San Francisco, 1906; member of the American Medical Association; fellow of the American College of Surgeons; on the staff of the Woodland Clinic Hospital, where he died September 6, aged 74.

Russell Milton Farnham, Glendale, Calif.; University of Minnesota Medical School, Minneapolis, 1922; president of the Glendale Branch of the Los Angeles County Medical Association in 1931; served overseas during World War I; interned at the Children's Hospital in Los Angeles; member of the board of directors of the Physicians and Surgeons Hospital; died September 11, aged 53.

Henry Sall Fischer, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1918; member of the American Medical Association; fellow of the American College of Surgeons; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; on the staff of the Beth Moses Hospital; died in the Beth David Hospital, September 21, aged 50.

Robert Joseph Flynn ⊕ Scranton, Pa.; Jefferson Medical College of Philadelphia, 1916; served overseas during World War I; for many years attached to the regional Veterans Bureau; for a time surgeon for the city police department, chief physician for the city gas and water company and deputy coroner; on the staff of the Scranton State Hospital, Mercy Hospital and St. Mary's Hospital, where he died September 28, aged 49, of cirrhosis of the liver.

John Fisher Gainer ⊕ Danville, Ill.; University of Illinois College of Medicine, Chicago, 1922; assistant in surgery from April to September 1922 at his alma mater; on the staffs of the Lakeview and St. Elizabeth hospitals; died October 21, aged 48, probably of coronary thrombosis.

Dewell Gann Sr. ⊕ Benton, Ark.; Southern Medical College, Atlanta, 1886; at one time vice president of the Arkansas Medical Society; president of the Saline County Medical Society; surgeon for many industrial plants and four railroads in Benton; died September 25, aged 82.

Robert S. Garnett, Tacoma, Wash.; Georgetown University School of Medicine, Washington, D. C., 1903; member of the American Medical Association; died in St. Joseph Hospital September 29, aged 68, of cerebral hemorrhage.

Frederick Christian Gerlach ⊕ San Jose, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; served during World War I; physician for the University of Santa Clara; died in the O'Connor Sanitarium October 4, aged 74, of heart disease.

Oramel E. Haney, Portland, Maine; Medical School of Maine, Portland, 1903; member of the American Medical Association; served during World War I; on the staffs of the Maine General Hospital and the Maine Eye and Ear Infirmary; died September 4, aged 68, of coronary thrombosis.

Henry Harmon, Pontiac, Mich.; Chicago Homeopathic Medical College, 1889; died October 29, aged 82, of cerebral hemorrhage.

Wayne Pearson Harrison ⊕ New York; University of Vermont College of Medicine, Burlington, 1928; specialist certified by the American Board of Ophthalmology; on the staff of the New York Eye and Ear Infirmary; died October 20, aged 49, of heart disease.

Benjamin Woodward Hazell, Baltimore; Maryland Medical College, Baltimore, 1905; died October 3, aged 73, of arteriosclerotic cardiovascular disease.

Charles Stephen Hoover, Cleveland Heights, Ohio; Western Reserve University Medical Department, Cleveland, 1901; served during the Spanish-American War and World War I; died in the University Hospitals, Cleveland, October 7, aged 69, of cardiovascular disease and probably coronary occlusion.

Alexander George Hough ⊕ Beaver Dam, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1905; served several terms as secretary of the Dodge County Medical Society; councilor of the first district of the State Medical Society of Wisconsin; served during World War I; died in St. Joseph's Hospital September 26, aged 75, of diabetic gangrene.

Orlan T. Hughes, Lexington, Ky.; University of Louisville Medical Department, 1909; member of the American Medical Association; died September 23, aged 63, of hypertensive heart disease.

John Hynds, Buffalo, Wyo.; University Medical College of Kansas City, Mo., 1908; served during World War I; formerly medical examiner for the Chicago, Burlington and Quincy Railroad; died August 2, aged 65, of chronic encephalitis lethargica.

Robert Moore Johnston, Ocoee, Fla.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; served one term as mayor of Ocoee; for eight years engaged in missionary work in West Africa; died September 18, aged 74, of heart disease.

Robert DuVal Jones Jr. ⊕ Norfolk, Va.; University of Pennsylvania School of Medicine, Philadelphia, 1924; member of the Southern Society of Clinical Surgeons; interned at the Robert Packer Hospital in Sayre, Pa.; formerly fellow in surgery at the Mayo Foundation and assistant resident surgeon at St. Mary's Hospital, both of Rochester, Minn.; affiliated with the Leigh Memorial Hospital; died in a hospital at Winston-Salem, N. C., September 5, aged 46.

Demeter Kalinoff ⊕ Stillwater, Minn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901; attending physician at the Minnesota State Prison from 1903 to 1935; on the staff of the Lakeview Memorial Hospital; died in the Miller Hospital, St. Paul, September 15, aged 74.

William R. Knabe ⊕ Orleans, Mass.; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1903; member of the Medical Society of the State of New York; died September 10, aged 66.

Wladyslaw August Kuflewski, Chicago; College of Physicians and Surgeons of Chicago, 1894; fellow of the American College of Surgeons; past president of the city public library board and past vice president of the board of education; for many years served as chief medical examiner of the Polish National Alliance; since 1902 chief surgeon of the Second Regiment of the Illinois National Guard; senior attending surgeon, St. Mary of Nazareth Hospital, where he died October 23, aged 75, of cerebral hemorrhage.

Alexander Kulchinsky, Chicago; Chicago College of Medicine and Surgery, 1916; died in the Columbus Hospital October 13, aged 77.

William Theodore Langley, Sanford, Fla.; Medical College of Alabama, Mobile, 1899; member of the American Medical Association; served overseas during World War I; at various times city and county physician; died September 11, aged 69, of cerebral hemorrhage and hypertension.

Hartland Law, San Francisco; Hahnemann Medical College of the Pacific, San Francisco, 1893; died September 27, aged 87, of coronary thrombosis.

Stuart Johnston Lawson, New London, Conn.; University of Virginia Department of Medicine, Charlottesville, 1905; member of the American Medical Association; on the staff of the Lawrence and Memorial Associated Hospitals; died September 8, aged 65.

Sidney Harold Levy ⊕ Buffalo; University of Buffalo School of Medicine, 1915; member of the Radiological Society of North America, Inc.; served during World War I; died in the Buffalo City Hospital September 22, aged 52, of bronchopneumonia and Parkinson's disease.

Jesse Herbert Libby ⊕ Weymouth, Mass.; Harvard Medical School, Boston, 1892; an Affiliate Fellow of the American College of Surgeons; served as a member of the school committee; on the staff of the South Shore Hospital, where he died September 25, aged 78, of arteriosclerosis and bronchopneumonia.

James Williamson Maloy, Rhine, Ga.; Hospital Medical College, Eclectic, Atlanta, 1911; died September 1, aged 60.

Albert Brown McKee ⊕ Redwood City, Calif.; Cooper Medical College, San Francisco, 1886; clinical professor of surgery (ophthalmology) emeritus at the Stanford University School of Medicine; died in Woodside August 19, aged 82, of heart disease.

Francis Joseph McMenamin ⊕ Oneonta, N. Y.; Long Island College Hospital, Brooklyn, 1907; on the staff of the Aurelia Osborn Fox Memorial Hospital, where he died October 2, aged 65, of coronary thrombosis.

James A. McVeigh, Detroit; Medical College of Ohio, Cincinnati, 1896; for many years physician for the city health department; associated with the Ford Motor Company Medical Center; died in the Henry Ford Hospital October 3, aged 73, of carcinoma of the liver.

Charles Price Mercer, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1891; formerly assistant medical inspector for the bureau of health; on the staff of the Stetson Hospital; died in the Episcopal Hospital September 19, aged 80, of bronchopneumonia and heart disease.

James Charles Millman, Platteville, Wis.; Northwestern University Medical School, Chicago, 1893; died October 9, aged 84, of myocardial failure.

Arthur Hugh Montgomery ⊕ Montgomery, Ala.; Atlanta Medical College, 1898; served as city physician; died in St. Margaret's Hospital October 5, aged 72, of coronary thrombosis.

William Edward Mulcahy, Boston; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1912; died September 2, aged 61.

Brian Francis Patrick Murphy, Baltimore; Georgetown University School of Medicine, Washington, D. C., 1943; interned at the Union Memorial Hospital; served as a fellow in pathology at the Johns Hopkins Hospital; died September 10, aged 30.

Henry Akin Nesbitt, Clarksville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1900; died September 23, aged 77, of cancer.

Alonzo Bond Persley, Detroit; University of Michigan Medical School, Ann Arbor, 1915; served during World War I; died in the Harper Hospital September 19, aged 54, of an old coronary thrombosis.

George Trecise Polk, Pittsburgh; Albany (N. Y.) Medical College, 1917; member of the American Medical Association; specialist certified by the American Board of Otolaryngology; in transport service during World War I; formerly on the staff of the Brooklyn Eye and Ear Hospital and consulting otolaryngologist at the Matteawan State Hospital, Beacon; on the staff of the Shadyside Hospital; died September 6, aged 50, of heart disease.

Russell Lee Pope, Richmond, Ky.; University of Louisville School of Medicine, 1932; member of the American Medical Association; president of the Pope Hospital, where he died October 14, aged 37, of injuries received in an automobile accident.

Lucien Griggs Rice ⊕ Albuquerque, N. M.; New York University Medical College, 1898; Cornell University Medical College, New York, 1899; past president of the New Mexico Board of Medical Examiners; on the staffs of the Presbyterian and St. Joseph's hospitals; died October 2, aged 70, of coronary thrombosis.

Thomas Duncan Robertson ⊕ The Dalles, Ore.; University of Oregon Medical School, Portland, 1930; member of the American Society of Clinical Pathologists; member and formerly president of the state board of health; formerly secretary of the Oregon State Medical Society; at one time on the staff of St. Vincent's Hospital in Portland; associated with The Dalles Clinic; died September 15, aged 42, of bronchopneumonia.

Benjamin D. Satek ⊕ Chicago; Chicago Medical School, 1917; for many years connected with the city department of health; died October 7, aged 62, of cerebral hemorrhage.

Charles Bushfield Schildecker ⊕ Pittsburgh; Columbia University College of Physicians and Surgeons, New York, 1901; served for a time as coroner's physician; for many years on the staff of the Western Pennsylvania Hospital, where he died November 12, aged 68, of coronary occlusion.

Harvey Frederick Scholl ⊕ Prospect Park, Pa.; Jefferson Medical College of Philadelphia, 1893; for many years school physician; on the staff of the Taylor Hospital, Ridley Park, where he died October 7, aged 74, of acute nephritis.

Walter Preston Scott, Lexington, Ill.; Keokuk (Iowa) Medical College, 1898; died in the Mennonite Hospital, Bloomington, September 16, aged 80, of a fractured hip received in a fall.

Ulysses Sheridan Short ⊕ St. Louis; St. Louis University School of Medicine, 1903; active on the council and past president and secretary of St. Louis County Medical Society; served in France during World War I; died October 18, aged 67, of cirrhosis of the liver and gastroenteritis.

Charles Elmer Shultz, Castle Shannon, Pa.; Maryland Medical College, Baltimore, 1911; member of the American Medical Association; served on the staff of the Southside Hospital in Pittsburgh; died in the Allegheny General Hospital, Pittsburgh, September 29, aged 64.

George Albert Sihler Sr. ⊕ Litchfield, Ill.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1883; since 1890 a member of the board of directors and since 1907 vice president of the First National Bank; for many years a member of the board of directors of the grade school; instrumental in establishing the city water department; died October 24, aged 83, of lymphosarcoma.

Richard Clyde Sinclair, Pine Lawn, Mo.; Washington University School of Medicine, St. Louis, 1933; first lieutenant, medical reserve corps, U. S. Army, not on active duty; died September 21 in the Missouri Baptist Hospital, St. Louis, aged 37, of bilateral lobar pneumonia, following an accident in which he incurred a fracture of the lumbar vertebra.

John Henry Slevin, Detroit (licensed in Michigan in 1901); member of the American Medical Association; fellow of the American College of Surgeons; served during World War I; deputy collector of internal revenue; member of the consulting staff of the Grace Hospital, where he died September 18, aged 73, of carcinoma of the esophagus.

David M. Sloan, Sturgis, Ky.; Louisville Medical College, 1898; member of the American Medical Association; past president of the Union County Medical Society; served on the staffs of Our Lady of Mercy Hospital, Morganfield, and the Sturgis Hospital, where he died October 10, aged 74, of uremia.

Charles Gregory Smith, Cincinnati; Eclectic Medical Institute, Cincinnati, 1890; formerly on the faculty of his alma mater; died in the Bethesda Hospital September 3, aged 75, of cerebral hemorrhage.

Henry Spence ⊕ Jersey City, N. J.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1892; fellow of the American College of Surgeons; past president of the state department of health; served as a member of the city board of health; member of the consulting staff of the Christ Hospital and the Margaret Hague Maternity Hospital; died in the Jersey City Medical Center November 22, aged 79.

William Albert Spencer ⊕ Wolcott, Ind.; Michigan College of Medicine and Surgery, Detroit, 1901; died October 3, aged 73.

Woodson Washington Spicer, Calhoun, Ky.; Louisville and Hospital Medical College, 1908; member of the American Medical Association; served as secretary-treasurer of the McLean County Medical Society; on the examining board of the Selective Service; died in the City Hospital, Owensboro, September 26, aged 65, of heart disease.

Robert Edward Sproule, St. Petersburg, Fla.; University of Dublin School of Physic, Trinity College, Dublin, Ireland, 1883; served in the medical corps of the British navy during World War I; died October 12, aged 88.

Gilbert H. Stannard ⊕ Sheboygan, Wis.; Milwaukee Medical College, 1904; past president of the Sheboygan County Medical Society; affiliated with the Sheboygan Memorial Hospital, where he died September 4, aged 69, of coronary thrombosis.

Daniel Freeman Stough Sr., Geary, Okla.; Illinois Medical College, Chicago, 1898; member of the American Medical Association; honorary member of the Oklahoma State Medical Association; served as a member and president of the school board, city treasurer and as mayor of Geary; died September 6, aged 70, of cerebral hemorrhage.

Peter Harold Sunde ⊕ Beverly Hills, Calif.; Jenner Medical College, Chicago, 1901; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; died October 8, aged 68.

Otto H. Swantusch ⊕ Angola, Ind.; Fort Wayne College of Medicine, 1905; served during World War I; died October 13, aged 61, of chronic myocarditis.

Annabel Cleveland Test, Chicago; Northwestern University Woman's Medical School, Chicago, 1895; died in the Passavant Memorial Hospital October 7, aged 74.

Bennie Everette Vowell, Carthage, Miss.; University of Tennessee College of Medicine, Memphis, 1914; member of the American Medical Association; died October 17, aged 52, of abscess of the lungs.

Rogers Fairbanks Wakefield, Pasadena, Calif.; University of Michigan Medical School, Ann Arbor, 1924; member of the American Medical Association; interned at the Los Angeles General Hospital in Los Angeles, where he had been a resident physician; member of the Los Angeles Dermatological Society; died September 2, aged 45, of coronary thrombosis.

Anthony T. Walsh ⊕ Scranton, Pa.; Baltimore Medical College, 1902; on the staff of St. Mary's Hospital; served during World War I; died October 12, aged 69, of coronary disease.

Harry Goldsborough Watson, Elmhurst, N. Y.; Yale University School of Medicine, New Haven, Conn., 1898; died in the Lenox Hill Hospital, New York, October 1, aged 76, of carcinoma of the rectum.

John Walter Webb ⊕ Indianapolis; Chicago Homeopathic Medical College, 1904; a member of the state board of medical examiners; on the staff of the Methodist Hospital; died October 9, aged 64, of coronary thrombosis.

Walter J. Werfelmann Sr., Syracuse, N. Y.; Syracuse University College of Medicine, 1890; member of the American Medical Association and the Syracuse Academy of Medicine; died September 2, aged 76, of carcinoma of the stomach.

Frank H. Westerschulte, Chicago; Rush Medical College, Chicago, 1895; died October 17, aged 79, of coronary thrombosis.

William Arthur Williamson, Duffee, Miss.; Mississippi Medical College, Meridian, 1907; killed October 26, aged 74, when struck by a freight train.

Charles Edwin Woods, Fitchburg, Mass.; Dartmouth Medical School, Hanover, N. H., 1890; member of the American Medical Association; past president of the Worcester North District Medical Society; served as school physician in Lunenburg and trustee of the Ritter Library; died in the Burbank Hospital October 12, aged 82, of bronchopneumonia.

Albert A. Yungblut ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1903; died August 21, aged 73.

LONDON

(From Our Regular Correspondent)

Dec. 15, 1945.

Fundamental Principles for the National Health Service

Though the government bill for a national health service has not yet been presented to Parliament, there is much controversy both in the lay and in the medical press. The negotiating committee of the medical profession, which is composed of representatives of the British Medical Association, the Royal Colleges of Physicians, Surgeons, Obstetricians and Gynecologists, the Royal Scottish Medical Corporations, the Society of Medical Officers of Health and the Medical Women's Federation, has agreed to certain fundamental principles of the medical profession, which should not be infringed on by any government proposals. With these conditions the profession should find no difficulty in working out a national health service in cooperation with the government.

For a quarter of a century the medical profession has stressed the need for a complete health service. It is willing and anxious to cooperate with the government in evolving this service, for its knowledge and experience are indispensable to success. It emphasizes that good housing and social, economic and environmental circumstances are the principal factors in maintaining health and preventing disease. It urges the expansion of medical research. In the interests of the public and of medicine the profession regards the following principles as essential: 1. In the public interest the profession is opposed to any form of service which leads directly or indirectly to the profession as a whole becoming full time salaried servants of the state or the local authority. 2. The profession should remain free to exercise the art and science of medicine according to its traditions, standards and knowledge; the individual doctor should retain full responsibility for the care of the patient and freedom of judgment, action, speech and publication without interference in his professional work. 3. The citizen should be free to choose or change his family doctor, to choose, in consultation with him, the hospital at which he should be treated, and free to decide whether he uses the public service or obtains independently the medical service which he needs. 4. Doctors should, like other workers, be free to choose the form, place and type of work they prefer without government or other direction. 5. Every doctor should be entitled to participate in the public service. 6. The hospital service should be planned in natural hospital areas centered at universities in order that these centers of education and research may influence the service. 7. There should be adequate representation of the medical profession on all administrative bodies.

Driving an Automobile While Under the Influence of Insulin

In 1930 a law was enacted making it an offense to drive a car while under the influence of drink or drugs to such an extent as to be incapable of proper control of the vehicle. The drugs concerned in the legislation were chiefly morphine and cocaine. The possibility of a diabetic motorist being charged with the offense of driving while under the influence of insulin was not considered. Such a case has occurred, and the man was convicted. A fine of $10 was imposed, and his driving license was suspended for a year. The man had not eaten his normal midday meal on the day of the accident. During the afternoon he felt tingling in the fingers and took a lump of sugar. He felt tired and decided to drive home. He thought that he drove normally and did not remember the accident. An appeal was made against the sentence. His lawyer argued that there was no proof of the unlawful influence of a drug. The motorist was right in taking insulin on medical advice and was not under the influence of the drug but of insufficient food. Medical evidence was given that insulin is a drug and the judge held that the motorist had rightly been convicted. As he was entirely blameless in the matter, he did not deserve punishment. The judge therefore dismissed the case under the Probation of Offenders Act and restored the license.

The Food Problem of India

The report of the Famine Commission of India appointed by the government is based on the principle that the state must recognize its ultimate responsibility to provide enough food for all, not only to prevent famine, but to insure a healthy and vigorous population. However, some people would regard the continued increase of an already dense population as an insuperable obstacle. The population of India has increased by 100 million since 1880, and a further addition to this number must be expected in another twenty-five years. Ultimately, the report states, the rate of growth will have to be decreased. To this end the commission envisages emigration to the more sparsely settled parts of the British commonwealth and empire and the encouragement of family limitation. The diet of most of the population is unbalanced, containing too little of protective foods, such as legumes, meat, fish and vegetables. Perhaps 30 per cent of the people do not have enough of both energy building and protective foods. The poorer classes, both urban and rural, could not afford a balanced diet, even if it was available. A long term policy should have the objective of self sufficiency in cereals, the basic food of the country, with control of their price. To balance the cereals the production of legumes, vegetable oils and fruits must be increased, and potatoes, sweet potatoes and platains should be grown in great quantity.

SWEDEN

(From Our Regular Correspondent)

Stockholm, Nov. 30, 1945.

Dextran

The Swedish press became incensed recently when it learned that some American physicians had stated that the Swedes had developed a new "miracle" blood substitute, called dextran, and were refusing to give out any information about it until a world patent had been acquired. A denial has now been issued saying that this is entirely false. According to Professor Arne Tiselius of Uppsala, in whose laboratory the blood substitute has been developed, there has been a definite misunderstanding. The substance dextran is well known, so there can be no question of the patenting of an "invention" in the usual sense. Dextran is a blood substitute which was developed two years ago in Uppsala and for fourteen months has been tried out clinically in hospitals in the cities of Stockholm and Örebro. Used in place of blood plasma at St. Göran's Hospital in Stockholm, it has been chiefly beneficial in cases of severe burns. Although the Swedish physicians have not yet dared to replace plasma with dextran entirely, it is hoped that the results of present experiments will warrant this shortly. In severe cases they have generally used equal parts of plasma and dextran and have been able to cure several patients whose entire bodies were covered with burns. During July and August alone, 6 patients with one fourth of their bodies severely burned by denatured alcohol were completely healed. In cases of shock, dextran has also shown excellent results. It is hoped that this new preparation will shortly be released to hospitals throughout the country.

Successful Action Against False Advertising Claims

In 1941 a bureau was established in Sweden to scrutinize all the advertising of "free drugs," i. e. drugs sold without prescription. This institution has contributed greatly to correcting all such advertising. A report has recently been published of its activities during 1944 in the daily and weekly press throughout the country. The cooperation of the press has been excellent.

Criticism was made against one or more advertisements of sixty-one "patent" medicines. The advertisements in 36 instances were corrected immediately and discontinued in 21. It was not necessary to take action against the advertisers. Generally, advertisers now ask for bureau approval before sending advertisements to the newspapers or before using them as labels or in packages as instructions. Most of the texts that have been corrected were not exaggerated or false but gave a misleading impression.

The bureau has also successfully dealt with direct or indirect publicity of merchandise such as food, reducing preparations and diet cures as well as electrical apparatus for rheumatism and arthritis. Nor has there been much difficulty with enclosures in packages or window displays. It has rarely been necessary to threaten any company or individual with denial of the use of the press.

Rare Diseases Found in Sweden

Leprosy has to all intents and purposes disappeared from Sweden, for as far as is known there are only 6 persons afflicted with the disease in the entire country. Four of them suffer from lepra anesthetica, 1 from lepra tuberosa and 1 from lepra mixta. Two of these cases were diagnosed as late as 1941 and 1944, and most of the patients are well advanced in age. Sweden's leprosarium was discontinued in 1940, so 5 of the patients are being cared for in their own homes and 1 at a home for the aged.

Another disease which Sweden has been free from for many years is spotted fever. A few cases have appeared recently, but there is no fear that it will reach epidemic proportions. A communication to doctors and others in health work has advised them of the problems which this strange (for Sweden) illness presents.

Tuberculosis in Oslo During the War

Despite the occupation of Norway and the extremely difficult living conditions throughout the war, a recent investigation of tuberculosis in Oslo during the war years has shown that there was no increased spread of this infection. It is assumed, perhaps justifiably, that this is the result of the intense campaign carried on by the Oslo Board of Health before and during the war. Although no increased spread of infection could be proved, since 1941 there has been a rather considerable increase in the morbidity of pulmonary tuberculosis. Men have been the most frequent victims, and a higher age group has been attacked. The average age of infection has changed from 10 to 15 years to the 25 to 30 age group and even higher. Simultaneously the morbidity and mortality have greatly decreased in childhood and youth and shifted to the older age groups.

New Course for Physicians

Ninety school physicians from all parts of Sweden had a rather unusual meeting in Stockholm recently. It was the opening of the first state course in school hygiene ever held here for doctors. Since there are about 900 school physicians in Sweden, the 10 per cent that attended may be considered a good representation. The questions discussed during the week's course included school hygiene, school food and the problem of too large classes. Until recent years only about 40 per cent of the children in elementary school have had proper care. It was not until 1943 that a director was appointed to coordinate the work for the entire country. This first course for school physicians is considered promising for the present and future care of the health of children in grammar schools.

Soviet Conference on Hypertensive Diseases

A conference on hypertensive diseases, the first since the war, was held recently in Gorkiy. The conference was attended by a large number of Soviet physiologists, pathologists, internists, neuropathologists and surgeons. The agenda contained a number of urgent problems, such as pathogenesis, symptomatology, treatment and prophylaxis of hypertensive states and problems of experimental hypertension. Professor Lang of Leningrad read a paper on etiology and pathogenesis of hypertensive disease. The paper dealt with modern concepts of hypertension, hypertensive states and hypertensive diseases which occupy an important place among disorders of the central nervous system. Professor S. S. Vail, colonel of the Red Army Medical Service, Leningrad, read a paper on pathomorphology of hypertensive disease. He showed that hypertension causes injuries principally to blood vessels of the heart (57 per cent cases), less frequently to those of the brain (26 per cent) and still less to blood vessels of the kidney (8.5 per cent). In his histopathologic studies he established the significance of damage to the nuclei and fibers of the vegetative nervous system. Some original data concerning changes in basic argyrophil substances in hypertensive states were presented by A. I. Smirnova Zamkova, corresponding member of the Ukrainian Academy of Sciences at Kiev. Argyrophil substances are important in the human organism, and many disorders of the nervous and vascular systems are related to the changes in argyrophil membrane.

Professor Smirnova Zamkova showed a number of photomicrographs demonstrating changes in argyrophil substances in preparations of the heart, large blood vessels, liver and lungs obtained from human beings suffering from hypertensive disease and from rabbits in which the pressor nerves had been removed. Professor N. I. Gorev of Kiev discussed his research on experimental hypertension obtained by interrupting the activity of the pressor nerves in rabbits and in dogs. Original experiments on the role of a hypertensive factor were reported by Professor D. E. Alpern, corresponding member of the Ukrainian Academy of Sciences. He showed that in sensitized animals spinal fluid acquires clearly defined properties which cause contraction of blood vessels. Professor A. M. Gruenstein read a paper on neurologic syndromes in hypertensive disorders and on the treatment of headaches. Headaches which occur in hypertensive disease, he believes, are due to cerebral edema, which frequently is caused by the dilatation rather than by constriction of the blood vessels, by paresis and not by a spasm, by lowering rather than by increasing the vascular tonus. Professor B. F. Zelenin, member of the Academy of Medical Sciences, discussed modern methods of treatment and prophylaxis of hypertensive disease, especially the social measures that have been adopted. Professor Zelenin pointed to the effectiveness of night sanatoriums for sufferers from hypertension. These were organized in 1942 and 1943 during the siege of Leningrad. Professor L. I. Vogelsohn of Moscow reported on the prognosis of work disability and work provisions for sufferers from hypertensive disorders. He presented data provided by a detailed study of a large group of patients on the reaction to labor processes in peace and war.

Professor N. N. Priorov, scientist and deputy peoples commissar for health, and Professor V. V. Parin, secretary of the Academy of Medical Sciences, were present at the conference.

RIO DE JANEIRO, Nov. 30, 1945.

Incidence of Amebiasis and Giardiasis in Rio de Janeiro

Dr. J. Lopes Pontes has just published a paper in which he reports the results of his investigations on the incidence of parasitism by Endameba histolytica and Giardia intestinalis in the population of the city of Rio de Janeiro. For this purpose he has studied 165 individuals, 62 of whom were patients of the Misericordia General Hospital with medical or surgical diseases of the circulatory, respiratory, digestive, urogenital or muscular systems, and 103 healthy persons taken at random among industrial workers, office clerks and officers and workers in the government printing office. The specimens of feces have been examined by the Faust zinc concentration and fluctuation method. Besides Endameba and Giardia, other less pathogenic parasites, such as Ameba coli, have been searched for. Of 165 people 57 have been found positive to Ameba coli, or 34.5 per cent (30.6 per cent among hospital patients and 38.8 per cent among healthy persons), 19 have been found positive to Endameba histolytica, or 11.5 per cent (12.9 per cent among hospital patients and 10.8 per cent among healthy persons) and 19 have been found positive to Giardia intestinalis, or 11.5 per cent (4.8 per cent among hospital patients and 15.6 per cent among healthy persons). Of the 19 carriers of Endameba 14, or 78.9 per cent, showed pathologic disturbances which might have been related to the intestinal infestation. None of them have ever suffered from typical dysentery. Of the 19 positive cases of parasitism from Giardia 15, or 78.9 per cent, were silent carriers of the parasite. Discussing the question of Endameba histolytica carriers, the author emphasizes the frequency of pathogenic symptoms, although atypical, and the almost constant presence of lesions of the colon. These persons should really be considered potential patients. Treatment to eradicate the Endameba is necessary from the standpoint of the individual and the community. Of 18 foodhandlers 2 have been found to be carriers of Endameba cysts. Dr. Pontes points out that the influence of the intestinal flora and the local and general resistance of the host are factors which explain the symptomatic graduation of human.amebiasis.

Bacteriologic Postmortem Investigation

At the Instituto Oswaldo Cruz of Manguinhos at Rio Drs. Guilherme Lacorte and Mário Santos did bacteriologic studies on the blood and spleen in 145 necropsies. The cultures were positive in 67 cases, and in 46 cases the isolated bacteria were the proved or probable cause of disease. The presence of bacteria in the blood and the spleen implies bacteremia at the time of death, according to the observations of Hunt and his co-workers. In the authors' cases the presence of bacteria in these two sites was related to anatomic lesions of bacterial origin. When the bacteria were present only in the spleen, bacteremia probably was not present at the time of death. In rare cases bacteria were isolated from the lesions and not from the blood and spleen. Bacteriologic examinations at necropsy may be able to establish the diagnosis of obscure and unnoticed infections.

Brief Items

At the Brazilian Academy of Sciences of Rio de Janeiro Dr. Carlos Foa, associate professor of physiology at the University of São Paulo, presented a film entitled "The Conditioned Reflexes in the Formation of Human Personality," an invaluable gift from the Russian physiologist Pavlov.

A new hospital for children, the Casa da Criança, has been opened at Cuiabá (population 57,000) in the state of Matto Grosso. The new institution is connected with the Matto Grosso state department of health.

Dr. Genival Londres has been appointed medical superintendent of the Misericordia Hospital of Rio de Janeiro. Dr. Londres is a leading practitioner of cardiology in this city. He succeeds Dr. Paulo Cesar de Andrade. Dr. Iseu de Almeida e Silva has been appointed head of the department of surgery of the Misericordia Hospital. Dr. Silva was one of the principal assistants of Dr. Paulo Cesar de Andrade in that department.

Personal

Dr. Oscar Riddle of the Carnegie Foundation, Washington, D. C., is now in Rio de Janeiro. He has given lectures at the auditorium of the Moncorvo Filho Hospital and at the Brazilian Academy of Sciences on "Some Aspects of the Estrogens" and on "Endocrine Organs and Human Constitution."

Dr. Antonio Maltez has been appointed professor of gynecology at the Medical School of Salvador in the state of Bahia. He succeeds Dr. Aristides Maltez, his father, who was a distinguished gynecologist in that city.

Dr. Austregesilo Filho, associate professor of clinical neurology at the University of Rio de Janeiro, has recently been elected a member of the National Academy of Medicine of Rio de Janeiro, where he succeeds Dr. Artidonio Pamplona. At the weekly meeting Dr. Austregesilo Filho read a paper on "Tuberous Sclerosis and Neurodiaplasia."

Dr. A. Lourenço Jorge, professor of surgery at the School of Medical Sciences of Rio de Janeiro, was honored at a meeting held by many physicians of this city because of his election to the Brazilian Academy of Military Medicine.

Dr. Carlos R. de Morais has been appointed professor of otorhinolaryngology at the Medical School of Salvador, in the state of Bahia. He succeeds his father, Dr. A. Rodrigues de Morais.

Dr. Augusto Brandão has just completed twenty-five years as professor of surgery at the Rio de Janeiro University. Several ceremonies took place on this occasion at the Santa Casa hospital, at the Brazilian College of Surgeons and at the University to honor Dr. Brandão. Dr. Augusto Paulino, Dr. Joaquim Britto, Dr. Arnaldo de Moraes and Dr. Genival Londres spoke at the ceremonies conveying to Dr. Brandão the commendation and applause of the Brazilian physicians for the valuable work he has done as a professor at the university and as a leader of modern surgery in Brazil.

Marriages

WILLIAM A. HERATH, Joliet, Ill., to Miss Marvis Ludeman of Elmore, Minn., at Wheaton, Ill., September 15.

NELSON MONTGOMERY SMITH, Winchester, Va., to Miss Catharine Lee Palmer of Urbanna, October 11.

ARTHUR FLETCHALL WOODWARD, Washington, D. C., to Miss Beth Harding of Kilmarnock, Va., August 25.

DOCTOR ERNEST WARD JR., Durham, N. C., to Miss Sara Dockery Henry of Lumberton, October 27.

THOMAS O. WHELESS, Louisburg, N. C., Miss Lois Brown of Rocky Mount in Atlanta, September 1.

WARREN JUSTIN TAYLOR to Miss Marjorie Marian Hutchins, both of Hanover, N. H., September 15.

ALEXANDER RUSH, West Chester, Pa., to Miss Carol MacD. Smith in Bryn Mawr, September 15.

LE ROY M. A. MAEDER, Philadelphia, to Miss Albertine M. Reichle of Detroit, November 11.

EDWARD N. ROBERTS, Pocatello, Idaho, to Miss Montez Kennedy of Lawton, Okla., August 5.

STUART HODGES WALKER, New York, to Miss Frances Marie Taylor in Atlanta, March 10.

HOWARD V. ZEIGEL to Miss Eleanor Mae Nelson, both of Cleveland, Miss., October 12.

Correspondence

AN EARLY OBSERVATION ON PENICILLIN

To the Editor:—Considering the interesting nature of the subject, it is a curious fact that those who have written about the discovery and development of penicillin have overlooked the report of a pioneer investigator.

The selective bacteria-inhibiting property of the mold Penicillium was observed and described by the physicist John Tyndall in the year 1875. His communication to the English Royal Society was published in part one of the *Philosophical Transactions* for 1876.

In section 7 of his essay on "Optical Deportment of the Atmosphere in Relation to Putrefaction and Infection" he relates:

> Adjacent to the closed cases was placed a series of three exposed tubes, containing a liquid prepared in precisely the same way. On the 4th of October the exposed tubes were all turbid, and swarmed with *Bacteria*. In two of the tubes they were distinctly more numerous and lively than in the third. Such differences between sensibly conterminous tubes, containing the same infusion, are frequent. On the 9th, moreover, the two most active charged tubes were in part crowned by beautiful tufts of *Penicillium glaucum*. This expanded gradually until it covered the entire surface with a thick tough layer, which must have seriously intercepted the oxygen necessary to the bacterial life. The *bacteria* lost their translatory power, fell to the bottom and left the liquid between them and the superficial layer clear. [The opinion that a pellicle destroyed subjacent bacteria by depriving them of oxygen had been expressed by Pasteur.]
>
> Another difference pointing to differences in the unseen life of the air, was shown by these tubes. The turbidity of the two mould-crowned ones was colourless, exhibiting a grey hue. The third tube, the middle one of the three, contained a bright yellow-green pigment, and on its surface no trace of mould was to be seen. It never cleared, but maintained its turbidity and its bacterial life for months after the other tubes had ceased to show either. It cannot be doubted that the mould-spores had fallen into this tube also, but in the fight for existence the colour-producing *Bacteria* had the upper hand. Six other tubes, similarly exposed, showed the grey muddiness: all of them became thickly covered with mould, under which the *bacteria* died or passed into a quiescent state, fell to the bottom, and left the liquid clear.

In section 25 of the dissertation he reports:

> The mutton [infusion] in the study gathered over it a thick blanket of *Penicillium*. On the 13th it had assumed a light brown colour, "as if by a faint admixture of clay"; but the infusion became transparent. The "clay" here was the slime of dormant or dead *Bacteria*, the cause of their quiescence being the blanket of *Penicillium*. I found no active life in this tube, while all the others swarmed with *Bacteria*.

In section 26 of his memoir Tyndall describes the cultural characteristics of "three different kinds of penicillium" and notes:

> The same absence of uniformity was manifested in the struggle for existence between the *Bacteria* and the *Penicillium*. In some tubes the former were triumphant; in other tubes of the same infusion the latter was triumphant.

One could say of Tyndall what Helmholz said of Thomas Young, "His idea lay buried and forgotten in the folios of the Royal Society until a new generation gradually made the same discovery." Tyndall, however, achieved fame as a physicist while still living and the University of Tübingen awarded him the degree of M.D. (honoris causa) in recognition of other contributions to medical knowledge.

RUSSELL F. MADDREN, M.D., Hackensack, N. J.

THE PETIT MAL EPILEPSIES

To the Editor:—In Dr. Lennox's article on the petit mal epilepsies, which appeared in the Dec. 15, 1945 issue of THE JOURNAL, he rightfully points out the close relationship between the pyknolepsies and the petit mal epilepsies. Dr. Jelliffe and I had come to the same conclusion as far back as 1935, when we reported our findings in the April issue of the *Archives of Neurology and Psychiatry* (**33:**752). At that time we had reviewed all the cases of pyknolepsy reported in the literature and added our own observations.

JOHN NOTKIN, M.D., Poughkeepsie, N. Y.

TREATMENT OF BLACK WIDOW SPIDER BITE

To the Editor:—On page 1016 of the issue of Dec. 8, 1945 there appears an article on treatment of the bite of a black widow spider which exemplifies an overzealous search for symptoms with an apparent lack of consideration for the comfort of the patient.

The most elementary knowledge of therapeutics would indicate treatment, the first suggested by Osler's Practice, which has been satisfactory to both the patient and myself during an experience extending over forty years of practice in a Southern rural region. One-fourth grain (0.016 Gm.) of morphine, repeated as necessary, will afford relief, and nature will do the rest. The statement that "six and one-half hours after the bite the patient still showed no sign of having obtained relief," while they had, probably in desperation, given one-half grain (0.032 Gm.) of codeine sulfate, suggests a prejudice against narcotics which is difficult for a country practitioner to understand. I frequently give even a child one-half grain of codeine, but I use the phosphate—it's soluble.

R. E. HALE, M.D., Bellamy, Ala.

Bureau of Investigation

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following is an abstract of one such order:

Diamonex Company.—This Chicago concern carried on a mail-order business in the sale of a product called "Diamonex." This, it represented, would, when used as directed, "safely, quickly and completely overcome distressing and dangerous symptoms" and "effect a satisfactory reduction in high blood pressure, regardless of the failure of previous treatment, however lengthy, or of the seriousness of the connected ailment." The nostrum was advertised in periodicals of national circulation and through written and printed matter sent through the mails. One claim called the product the "discovery of a heart specialist," another "the private formula of a recognized heart specialist" which "has been tested clinically for several years . . . at a hospital," and still another assertion was that "results are speedy—within as short a time as two weeks sufferers often find that Diamonex has accomplished 75% of the total reduction possible with this formula." There was also included in the circular matter something entitled "Extract from report of clinical investigation on Diamonex," but since no source was given for the controls, this naturally means nothing. Of course, there were the usual testimonials and a money-back guaranty. An investigation of the scheme by the Post Office Department culminated in a hearing held in Washington in February 1944, at which one Martin Coughlin and an attorney were present to represent the Diamonex Company. The attorney was sworn as a witness, but did not testify. One government witness was a chemist of the Food and Drug Administration, who testified that his analysis of Diamonex tablets did not materially differ from the formula printed on the label, showing the presence of sodium nitrite, aminophyllin and carbromal. Two Senior Medical Officers of the same federal agency testified that high blood pressure is the result of various causes, some of which are as yet unknown; that proper scientific diagnosis of the condition calls for thorough physical examinations, X-rays and laboratory tests, so that the cause of each case may be ascertained and removed if possible, and that there is no single therapy which could be used scientifically in all cases of the condition, since they require highly individualized treatment. They testified, further, that of the three declared ingredients of Diamonex, sodium nitrite is known as a vasodilator, aminophyllin as a stimulant, and carbromal as a sedative; that the first-named, though capable of dilating some blood vessels, does not affect the particular ones causing the high blood pressure, those known as arterioles, and hence is useless in treating the condition, as well as objectionable in that it interferes with the proper functioning of the kidney; that aminophyllin, though a stimulant and a dilator as well, is of no value in treating hypertension, and either does nothing further for the condition or raises the pressure by the extra load which it puts on the heart, and that the third ingredient, carbromal, is not present in Diamonex in sufficient amount to produce sleep, will not relieve sleeplessness, restlessness or nervousness, or be of any value in treating hypertension. The Diamonex concern replied through its attorney's brief that the representations made in its literature as to the product's effectiveness in treating high blood pressure did not justify the charges made against it by the Post Office Department, but a review of the advertising showed this claim to be invalid. On May 25, 1944, the Post Office Department issued a fraud order debarring the Diamonex Company and its officers and agents from the mails.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Drunkenness: Probative Value of Chemical Tests Showing Nonintoxication Is Question for Jury.—The plaintiff, Dashiell, sued for damages to his automobile resulting from a collision with one of the defendant's busses, the collision allegedly having been caused by the negligent operation of the bus. From a judgment in favor of the plaintiff, and an order denying defendant's motion for a new trial, the defendant appealed to the court of appeals of Georgia, division number 2.

At the trial the defendant contended, among other things, that the plaintiff was under the influence of intoxicating liquor at the time of the accident. This the plaintiff denied, although he admitted to having taken two or three social drinks of whisky during the evening prior to the accident. To rebut defendant's contention further, however, the plaintiff offered the testimony of Lieutenant Sackett, a chemist at Camp Wheeler. The witness qualified as an expert by stating his long experience in laboratory work and in the laboratory department of Camp Wheeler, Georgia. He testified that he had performed a blood alcohol test of the plaintiff about an hour and a half after the accident and that the test was made according to the standard method used by the United States Army in making such blood tests. He stated that in his opinion, based on the results of such test, the plaintiff was not so under the influence of liquor at the time of the accident as to affect his ability to drive an automobile properly. The specific result of the test was not stated in the report of this case. Defendant objected to the admission of this testimony on the ground that it was irrelevant, immaterial, prejudicial and of no probative value.

The court of appeals held, in effect, that such testimony was neither irrelevant, immaterial nor prejudicial and said that under the circumstances the evidence was properly admitted and that its probative value was to be determined by the jury. The jury found for the plaintiff. We are of the opinion, said the court, that the verdict is authorized by the evidence. The judgment for the plaintiff was accordingly affirmed.—*Macon Busses, Inc. v. Dashiell, 35 S. E. (2d) 666 (Ga., 1945).*

Workmen's Compensation Acts: Conflict in Medical Testimony No Bar to Award for Hernia.—The claimant filed for compensation for injuries resulting in a hernia alleged to have been sustained during the course of his employment with the Bell Aircraft Corporation, and from an award in his favor the defendant corporation and its insurer appealed to the court of appeals of Georgia, division number 1.

The undisputed testimony of the claimant showed that, while pushing a rack weighing some 800 pounds, he strained himself and felt as though he had pushed something loose down in his groin. He did not associate the pain with either side but stated that he was in pain all over the lower part of his stomach. This occurrence took place on Jan. 15, 1944, and the claimant, on notifying the foreman of the circumstances, was immediately sent to Dr. Bailey, one of defendant's physicians, for first aid treatment. Dr. Bailey found that the claimant was suffering from a hernia and prescribed a suspensory for the claimant to wear. Claimant continued to work at lighter work up to March 1, 1944, but on that date he returned to his home and remained in bed most of the time for ten or eleven weeks. On April 4 claimant visited Dr. Coker, not one of defendant's physicians, and was found to be suffering from a hernia. Dr. Coker secured a truss for the claimant to wear which enabled the claimant to do some light work as a carpenter and to do a little work around his farm. He testified that his stomach and groin still pained him at that time, however. In conclusion the claimant stated that he was in need of an operation for hernia, was at the time of the hearing seeking such an operation and that he had never refused any operation nor been offered one by the defendant.

Dr. Brown, another of defendant's physicians, was the only physician who testified at the hearing, the medical evidence being substantially as follows: Dr. Bailey found a hernia on the left side as a result of his examination made on January 15, the date of the accident. Dr. Brown found no hernia to exist on the date of February 28, when he examined the claimant. He further testified, concerning his own examination, that the claimant had given a history of kidney stones on the left side at the age of 20 and also a history of having a back injury following a motorcycle accident. Dr. Coker, who examined the claimant on April 4, found an inguinal hernia on the right side. Dr. Wiseley, also one of the defendant's physicians, examined the claimant on May 8, 1944 and found nothing wrong with the claimant. Dr. Wiseley, it appeared, had examined the claimant because he wanted a medical release, but this was refused. Finally Dr. Brown testified that an examination of the claimant at the time of the hearing disclosed a right inguinal hernia. Dr. Brown was unable to answer as to why Dr. Bailey found a hernia on the date of the accident, whereas the witness was unable to find one on February 28, nor could he explain why Dr. Coker found an inguinal hernia on the right side on April 4, whereas Dr. Wiseley found nothing wrong with the claimant on May 8.

On the basis of this evidence the director found that the claimant was suffering from a hernia as a result of the accident on January 15, that said hernia occurred immediately after the accident, that said accident had not aggravated a preexisting condition that the claimant may or may not have had as a result of a motorcycle accident or kidney stone, and that the hernia existed at the time of the hearing. In making an award in favor of the claimant the director also ordered the defendant to tender adequate medical care and hospitalization for the repair of the right inguinal hernia.

The defendant's assignment of error was to the effect that there was no competent evidence to support the award, the gist of the contention being that the director at the hearing had taken into consideration the hearsay testimony of Dr. Bailey, who had not been sworn as a witness. Dr. Brown, said the court, was sworn in as a witness and was questioned at length by the director and the attorney for the claimant concerning the contents of Dr. Bailey's report and Dr. Bailey's findings. No objection was made during the entire hearing as to the admissibility of Dr. Bailey's findings. Furthermore, continued the court, even if such testimony was hearsay and was admitted with or without objection, it would not require the setting aside of the award in favor of the claimant. Without considering this testimony, concluded the court, there was evidence to support the award of the compensation commission. Accordingly the award in favor of the claimant was affirmed.—*Hartford Accident & Indemnity Co. v. Hillhouse, 35 S. E. (2d) 603 (Ga., 1945).*

AMERICAN BOARD OF UROLOGY: *Oral.* Chicago, February 1946. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Work of Tissue Survey Committee. T. C. Moss.—p. 344.

Measles Pneumonia.—According to Milles, pneumonia is a common occurrence in measles and it often assumes such a characteristic form that it should be regarded as an integral part of the disease rather than a complication. Milles reports the histories of 2 adults who died late in the course of measles pneumonia. Results of necropsy on these 2 cases emphasize the anatomic specificity of measles pneumonia. The pulmonary lesion of measles results from extension of the lesion of the mucous membrane along the bronchial tree to the finer ramifications. The partial obstruction of the smaller passages by desquamated epithelium and mucus leads to conversion of the process from a catarrhal inflammation, characteristic of the larger air passages, to a purulent process. Extension into the peribronchiolar tissues and into the neighboring alveoli results in a bronchopneumonia, which may be disseminated and discrete or may become confluent. In either instance the process is specific if one may interpret the presence of even a rare Alagna giant cell as specific for measles. The roentgenogram of the disseminated process is not unlike that seen in miliary tuberculosis or rarely in atypical pneumonia. The Alagna giant cell with its bare agglomeration of eight or more nuclei is apparently specifically found in measles and was noted in the reported cases as late as the twenty-fourth day of the disease.

Unusual Clinical Syndrome Following Ingestion of Fish. H. Schneck.—p. 347.

Disappearance of Peptic Ulcer After Feeding of Normal Gastric Juice.—Morrison removed gastric juice from normal subjects and fed it to patients with peptic ulcer. Normal gastric juice was obtained from 6 volunteer subjects. The juice was rendered neutral by sodium hydroxide, filtered and rendered bacteriologically sterile by 0.3 per cent tricresol as a preservative. Ten patients with uncomplicated peptic ulcer roentgenologically demonstrable as a niche, a crater or an ulcer defect, in addition to the associated x-ray findings such as spasm, increased emptying time and local pain to palpation under fluoroscopic guidance, were placed on a well balanced diet. One half ounce of normal gastric juice diluted with 2 ounces of tap water was fed to each patient every hour during waking hours. No other medication was given. Eight of the 10 patients responded in from twenty-four to forty-eight hours to the feeding of normal gastric juice by becoming free from ulcer symptoms. No ulcer recurrences have occurred in these 8 patients during a three year follow-up period. Of the 2 patients who showed no improvement, 1 had had ulcer symptoms for nineteen years and the other intermittently for twenty-five years. The author concludes that a "protective principle" is elaborated within the gastric and duodenal mucous membranes and is secreted into the gastric juice. This protective principle may be lacking or impaired in patients with peptic ulcer, but it can be fed to them, causing the ulcers and symptoms to disappear.

Effect of Fatigue, Chilling and Trauma on Resistance to Poliomyelitis.—Levinson and his associates found that monkeys subjected to exhausting exercise or to chilling during the incubation period of experimental poliomyelitis developed a higher incidence and more severe paralysis than controls. Monkeys subjected to trauma of one or more limbs during the incubation period of experimental poliomyelitis showed no correlation with the location of the paralysis, and the severity and extent of paralysis did not differ from the controls. The incidence and severity of paralysis was significantly greater in monkeys inoculated with the virus during the summer months.

Influence of Sulfonamides on Epidemicity of Subclinical Pneumococcic Infections.—Siegel and Karr studied over a period of eighteen months the nasopharyngeal pneumococcic flora of 60 normal children, of whom half were treated with sulfadiazine for fifteen consecutive weeks and half were untreated. Fluctuations in the frequency of different predominant pneumococcus types were observed which were unaccompanied by recognizable symptoms and resembled a succession of subclinical epidemics affecting from 53 to 97 per cent of the persons exposed. Chemotherapy modified the normal frequency trend of susceptible strains and initiated generalized carrier epidemics of resistant strains. Therapy affected the prevailing ratio of drug susceptible pneumococci to drug resistant strains, which eventually readjusted itself after treatment. The authors conclude that the epidemicity of nasopharyngeal pneumococcic infections is inherent in strains of different degrees of virulence and can be profoundly altered by selective chemotherapy.

Immunization of Diphtheria Carriers.—Roshkovskaya and Shumakova studied the problem of immunization of carriers in a large group of school children who were exposed to 15 cases of diphtheria. Immunization and bacteriologic studies were preceded by Schick tests. The follow-up lasted six months. The Schick test was positive in 143 of 495 children examined. In the course of six months the positive Schick reactors were examined three times. The first examination was carried out prior to immunization, the second examination one month and the third examination four months after the last vaccination. The proportion of positive cultures remained almost unchanged four months after immunization (23.2 per cent versus 24.7 per cent) but the carrying of virulent bacilli greatly changed. Thus, in the examination prior to immunization 16.3 per cent of the total cultures were of the virulent type in these carriers. One month after immunization there were 4.5 per cent and after four months only 2.8 per cent of the total number of cases. Avirulent bacilli increased correspondingly from 8.4 per cent (first examination) to 20.4 per cent (third examination). Whether the virulent bacilli are transformed into avirulent ones or whether reinfection with avirulent forms occurs remains a question. A comparison was made of diphtheria carriers in Schick positive and Schick negative children. Of the 143 children with positive Schick reactions 25.2 per cent, and of 352 Schick negative children 12.8 per cent were carriers of virulent bacilli. The greatest incidence of virulent carriers was found in children with a 1 plus Schick reaction; none were found in highly susceptible (Schick 3 plus) children.

Endocarditis Treated with Penicillin.—In 1942 Goerner and his associates employed small doses of penicillin in the treatment of 4 patients with subacute bacterial endocarditis. All of the 4 patients so treated died from six weeks to twelve months later. In 1944 the authors used larger doses. The plan was to give each patient about 240,000 units of penicillin daily for three to four weeks. A larger dose or longer course might be indicated by unusually high resistance of the infecting organism to penicillin in vitro, unsatisfactory serum penicillin levels or unfavorable clinical course. Each patient received 5,000,000 or more units of penicillin. Of 12 patients so treated 11 are alive and well, and in several instances more than a year has elapsed since termination of therapy. Heparin proved unnecessary, nor did its use alter the outcome of the single unsuccessful case. Of the three parenteral routes of administration—continuous intravenous infusion, continuous intramuscular infusion and intermittent intramuscular injections at two hour intervals—the first was the most satisfactory. The authors conclude that penicillin alone is an effective therapeutic agent in subacute bacterial endocarditis when the infecting organism is inhibitable by penicillin and the conduct of treatment is carefully determined in each individual case.

Thiouracil in Hyperthyroidism.—Gabrilove and his associates employed thiouracil in the treatment of 51 patients with hyperthyroidism and of 3 patients with nontoxic goiter. Thirty-three of these patients have been treated successfully with thiouracil for varying periods of time, the longest period of continuous therapy being ten months. Four of these patients had recurrent hyperthyroidism, the remainder having diffuse hyperplasia or toxic nodular goiter. Three patients with hyperthyroidism were successfully prepared for operation with thiouracil. Four patients with hyperthyroidism failed to respond satisfactorily to thiouracil. These patients were subsequently prepared with iodine and successfully operated on. In 11 instances thiouracil therapy was discontinued because of severe toxic reactions. Toxic reactions encountered were conjunctivitis 5 cases, edema 1 case, drug fever 4 cases, leukopenia 1 case and agranulocytosis 6 cases. Toxic reaction in some form was encountered in nearly one third of the patients. One patient with agranulocytosis died. The authors feel that because of the frequency and severity of toxic reaction, thiouracil should be used under the following circumstances: in the preparation of iodine-fast patients for operation, in older persons with hyperthyroidism who are poor operative risks, and in patients with recurrent hyperthyroidism who have been operated on twice or more.

Werner's Syndrome and Rothmund's Syndrome.—Thannhauser designates Werner's syndrome and Rothmund's syndrome as heredofamilial disorders. Many cases are reported in the literature under the misleading designation "scleroderma and cataracts." The skin changes in Werner's syndrome are not those of true scleroderma. Because of its recessive heredofamilial occurrence it is suggested that the skin changes, as the other symptoms of Werner's syndrome, are the result of a defective germ plasm not manifesting itself until the second and third decades of life. The designation of the disorder as "progeria of the adult" is suggested, since all symptoms of Werner's syndrome result in presenility. The designation of the skin changes as "heredofamilial atrophic dermatosis with skin ulcers" seems more appropriate. The skin ulcers in Werner's syndrome are not entirely trophic in origin since they appear only on exposed parts and are probably the result of pressure on the thin, atrophic and stretched skin. The success of grafting supports this opinion. The skin changes of Rothmund's syndrome are classified in the literature as poikiloderma or scleropoikiloderma. Such a classification does not accord with the heredofamilial occurrence or with the microscopic aspects. The author suggests for the skin changes in Rothmund's syndrome the term "heredofamilial atrophic dermatosis with telangiectases." Both syndromes may occur in incomplete forms. The heredity in both is recessive. The occurrence in brothers and sisters of one generation is often observed. Rothmund's syndrome starts usually in childhood, Werner's syndrome in the second and third decades. The author rejects the suggestion that Werner's and Rothmund's syndromes represent a purely ectodermal dysplasia or a primary endocrine functional disturbance. The recessive heredity of both syndromes suggests the existence of multiple germ plasm defects manifesting themselves in abiotrophic features of various organs at different periods of life.

Ulcer Problem.—The ease of production of perforating gastric and/or duodenal ulcer in animals by the implantation of histamine in beeswax emphasizes the importance of the acid-peptic digestive activity of the gastric juice in ulcer genesis. Fat embolism may occur following fracture of long bones and plug the end vessels of the gastric mucosa and produce erosions and/or ulcer, which in turn in the presence of active gastric secretion may result in bleeding, hematemesis and/or melena. This has been observed clinically and has been produced experimentally. The production of severe bleeding from erosions and/or ulcer attending the administration of vasospastic agents such as epinephrine or pitressin accompanied by histamine in beeswax definitely suggests the important role of the ischemia resulting from an overactive vasomotor influence in ulcer genesis when attended by active gastric secretion. Partial obstruction to the venous outflow from the stomach increases the weight of the stomach as a result of the ensuing edema of the gastric wall, especially of the submucosa. Such venous obstruction abets the ulcer diathesis. Bleeding gastric and/or duodenal erosions and/or ulcers, as well as erosions of the lower end of the esophagus, may be produced by such obstructions. The threatening bleeding of portal vein obstruction may be corrected by an operation (90 per cent resection) which reduces the capacity of the stomach to secrete. Wangensteen carried out this operation on 4 patients. Occult hemorrhage from the alimentary canal frequently has its origin in the stomach, and gastric resection is indicated in many such instances. This procedure was carried out successfully in 4 cases of profound occult anemia. The histamine in beeswax technic has proved a useful instrument in appraising the characterization of a satisfactory operation for ulcer. A three-fourths resection carried out on the Billroth II plan of operation, employing a short afferent duodenal loop in which the antral mucosa and the lesser curvature of the stomach are excised, meets the requirements of a satisfactory operation for ulcer.

*Observations on Use of Thiobarbital as Antithyroid Agent in Treatment of Graves' Disease. E. B. Astwood.—p. 345.

Thiobarbital as Antithyroid Agent.—Astwood states that 1 of each hundred patients treated with thiouracil has developed agranulocytosis and as a consequence 1 in a thousand has died. The more common reaction from thiouracil, drug fever, while not a serious complication, usually requires that the drug be discontinued and the disease must be treated in some other way. Thiobarbital (5,5-diethyl-2-thiobarbituric acid) has been used in man. The author treated 30 patients with hyperthyroidism with thiobarbital. Total daily doses of from 0.1 to 0.4 Gm. were given. All of the manifestations of hyperthyroidism were satisfactorily controlled, but in the dosage used there was a high incidence of complications. Two deaths occurred, one from agranulocytosis and one from an acute liver disorder; 6 patients experienced a febrile reaction during the second week of treatment. It is estimated that thiobarbital is more than twice as active as thiouracil in inhibiting the function of the thyroid but that it is more toxic than thiouracil when the minimal effective dose is exceeded.

Penicillin Levels During Systemic and Local Therapy.—Ory and his associates determined concentrations of penicillin in serum and certain body fluids of adult medical patients after administration of various doses of commercial penicillin given by different routes. The data were obtained almost entirely on patients while they were under treatment. When compared with the results of tests for sensitivity of the offending organism, such information helps to indicate the results to be expected from therapy in various types of cases. During continuous intravenous or intramuscular administration fairly constant levels are maintained in the serum of any given patient, but the levels may vary in different patients on the same dose. During intermittent intramuscular injections a range of serum levels but not exact values can be predicted for the interval between doses on any given dosage schedule. Larger doses result in serum levels which are sustained longer and at higher values than smaller ones. During intramuscular penicillin therapy it was not possible to detect penicillin in the cerebrospinal fluid, and the levels in pleural, peritoneal and synovial fluids were erratic and usually lower than the serum levels. Diffusion from local injections of penicillin into body cavities or into the serum is quite erratic, but adequate concentrations usually remain in cerebrospinal, pleural and pericardial fluids for twenty-four hours and sometimes for forty-eight hours or longer after local injections of large amounts. After inhalation of penicillin from nebulized solutions, small amounts may be detected in the serum for short periods but rarely for as long as two hours.

Electric Shock Therapy.—Lowinger and Huddleson treated 150 cases at the Veterans' Facility of Northport, N. Y., utilizing Kalinowsky's technic of electric shock therapy. Kalinowsky's plan of giving an immediate second shock, if grand mal failed to appear within a few seconds, was followed during the first thirteen and a half months. Doubling of shock was then discontinued as possibly contributory to accidents. Kalinowsky stressed the adequacy of treatment for dementia precox and favored a minimum course of twenty attacks of grand mal. The fracture prophylaxis employed by the authors has been limited to sandbags in graduated sizes. Active tuberculosis, cardiac or nephritic disease, thrombophlebitis, arteriosclerosis, osteoarthritis or bone atrophies, malignant disease, organic brain disorder and epileptic predisposition were accepted as contraindications to shock therapy. An average of seventeen attacks of grand mal was induced in 150 patients, 125 of whom had dementia precox. Of these 125 patients 21 were quiescent or much improved, 19 were improved and 85 were unimproved. The percentage of improvement was largest in cases of less than six months' duration. Of those cases which had lasted more than two years, none achieved a remission or were improved. Of 4 patients with miscellaneous psychoses, 3 were quiescent or much improved and 1 was unimproved.

*Pylephlebitis Under Penicillin and Sulfadiazine Therapy. A. O. Wilensky.—p. 2082.

Orthostatic Albuminuria.—Friedman and Read report a case of the lordotic type of orthostatic albuminuria. In 5 patients with orthopedic disorders wearing hyperextension body casts, repeated urine studies were negative for albumin, and renal function remained unimpaired. Six patients with unrelated medical and surgical conditions were placed in exaggerated lordosis for periods of one to two hours. All of these patients had negative urine studies, and the appearance of albumin could not be induced. The authors conclude that although lordosis plays a role in the pathogenesis of orthostatic albuminuria in susceptible individuals it is of no influence in producing albuminuria in normal, nonsusceptible individuals.

Penicillin and Sulfadiazine in Pylephlebitis.—A middle aged man who was operated on for acute suppurative appendicitis continued to have hyperpyrexia for four weeks, which suggested a subphrenic abscess, but an exploratory aspiration of the subphrenic space was negative. At the end of six weeks the patient presented fever and chills, enlargement of the liver with jaundice and slight functional disability, enlargement of the spleen, absence of ascites, and bacteriuria. He was given large doses of penicillin and sulfadiazine and recovered. Wilensky states that the history, postoperative course and the physical and laboratory findings were characteristic of a phlebitis of the portal vein complicating suppurative appendicitis. Enlargement of the spleen and an observed episode of pain in the splenic area with renewed enlargement of the spleen and the accompanying elevation of temperature indicated that the phlebitis spread into the splenic vein and caused infarction of that organ.

War Psychology and Postwar Perspective. L. J. Moorman.—p. 427.

Familial Aspects of Gout, Diabetes Mellitus and Obesity.—Ishmael investigated family histories of 50 patients with gouty arthritis who were seen at the McBride Clinic and the Oklahoma State University Hospital. He also investigated 50 patients with diabetes mellitus and 50 patients with various types of arthritis other than gout. Fifty consecutive patients with fractures served as controls. The results indicate that patients with gout, as well as those with diabetes mellitus, have a familial background of diabetes with relatively the same incidence. Of 7,768 patients admitted to an army air force station hospital 6 had gouty arthritis, and 5 of these had diabetes mellitus in the immediate family. All listed obesity as a familial characteristic. There exists a faulty metabolism of fats in both diseases. Ketosis is capable of precipitating complications in either disease. Factors likely to produce exacerbations are infections, surgical procedures, exhaustion, ketosis, emotional upsets and exposure. Arteriosclerosis results with high frequency. The younger the patient at the onset of either disease, the more severe is the course apt to be. Nephritis is a likely final complication in both diseases. The patients themselves are apt to be of more than average weight at the onset. Furunculosis appears frequently as a complication and occasionally leads to the diagnosis of diabetes mellitus or gout.

Putrid Empyema Without Foul Sputum.—Putrid empyema without a foul sputum is not rare. Neuhof and Stats encountered a considerable number of such cases. Diagnosis of putrid empyema in the absence of foul sputum or other evidence of a pulmonary abscess is difficult. The lesion should be suspected and efforts at diagnosis persisted in when certain clinical manifestations are present. Prolonged delay in diagnosis may be fatal. The variable clinical manifestations consist primarily of persistent chest pain, slight cough and expectoration, and an illness which is severe at least in the initial stage. Cough may be absent and the course chronic. Discovery of foul pus by aspiration of the pleura is the sole method of establishing the diagnosis. This disclosure will often be a surprise. Wide drainage of the main lesion and its ramifications will effect a cure unless the diagnosis has been delayed too long. A putrid pulmonary abscess is the precursor of "a surprise" putrid empyema.

Pulmonary Embolism in Fractures of Hip.—Golodner and his associates report 86 fatalities among 304 patients with fracture of the hip. Necropsies on 25 revealed that 9 cases were due to pulmonary embolism, 8 to bronchopneumonia, 3 to arteriosclerotic heart disease, 1 to a hemorrhage from a duodenal ulcer, 1 to sepsis from a wound infection, 1 to sepsis from a severe purulent prostatitis, 1 to pyelonephritis and 1 to voluntary starvation in a demented woman. Pulmonary complications were detected in more than two thirds of the necropsies, and over half of these were pulmonary emboli. Fatal pulmonary embolism from venous thrombosis in the veins of the lower extremities is the most frequent cause of death in cases of fracture of the hip. Venous thrombosis and embolism are less frequent in patients who are made ambulant early. Prophylactic bilateral superficial femoral vein ligation combined with lumbar sympathetic block is suggested as ideal for the prevention of pulmonary embolism in fractures of the hip, especially for patients who cannot be made ambulant early.

Penicillin in Progressive Bacterial Synergistic Gangrene.—According to Meleney and his co-workers, progressive bacterial synergistic gangrene is now accepted as a clinical entity. Meleney in 1926 found that the essential bacterial agent was a microaerophilic nonhemolytic streptococcus which was present in pure culture in the advancing periphery of the lesion in 1 of the cases which Brewer and he reported. This organism was associated with a hemolytic Staphylococcus aureus in the gangrenous margin. The combination of the streptococcus and the staphylococcus was shown to produce in animals a gangrenous lesion simulating the process in human beings. This lesion could be obtained only when the organisms were combined, thus demonstrating their synergistic action. The lesion usually begins around tension sutures placed in a wound of the abdominal wall or chest which has been made for the purpose of draining either an intraperitoneal or an intrapleural abscess. The skin around the tension suture becomes red, swollen and tender and takes on a dusky appearance resembling a carbuncle with a slowly developing necrosis of the skin. This occurs from ten to twenty days after the wound has been made. Removal of the tension sutures at that time does not control the infection, which spreads and gradually produces an ulcer. Surgeons have attempted to trim away the dead tissue but, without a radical removal well beyond the zone of erythema, recurrence follows. The sulfonamides have not been effective in controlling this condition, but penicillin not only prevents a recurrence after the excision but may obviate the necessity for excision by halting the progress of the lesion and permitting a spontaneous separation of the slough. This has been demonstrated in 2 patients. In a third patient with multiple lesions, penicillin cut down the exudate and probably had some antibacterial action on certain of the bacterial species, but the presence of gram negative rods prevented its control of the infection. Surgical removal of a great part of the diseased tissue was tolerated and the postoperative course was satisfactory up to the time of the pulmonary embolus. The authors do not feel that failure in this case detracts from the value of penicillin in this disease but emphasizes the necessity of a complete bacteriologic analysis.

Intrapapillary Renal Calculi.—Whipple removed calculi from the lower right ureter of a woman aged 21. The postoperative course was uneventful. On retrograde study a large (1.5 cm.) calculus was seen in the pelvis and numerous small calculi in the region of the lower major calix. A retrograde aerogram visualized the large pelvic calculus clearly. Nephrectomy was carried out. The lesion was identified as acute pyelonephritis and chronic papillary fibrosis with retention calculi. Bisection of the organ revealed that the lower major calix contained a papilla studded with many small calculi. As the gross contour of the papilla was well preserved, the specimen suggested the possibility of intratubular or intertubular calculus formation in contradistinction to the ultimate result of calculus formation through a gradual process of erosion and penetration from the caliceal surface.

Risks Involved in Use of Flexible Gastroscope.—Fletcher and Jones had 2 fatalities attributable to gastroscopy and 4 cases with pain and fever following gastroscopy. In the first case gastroscopy was probably contraindicated, since the tissues might have been expected to be in a fragile state as a result of recent scurvy. It is possible that the tear was the result of stretching the esophagus by the rigid part of the instrument, since the patient had a slight kyphosis. In the second case extra pressure was exerted when the tip of the instrument was lying in the hypopharynx. When the patient swallows, the instrument should always slip on easily into the esophagus, and it is clearly dangerous to apply pressure if it does not do so. In addition to these 2 fatal cases and the 4 in which severe retrosternal pain and fever followed gastroscopy, the authors have heard of 5 other fatal and 2 nonfatal cases of hypopharyngeal perforation of the esophagus by the flexible gastroscope during the past two years. They stress that inexperienced gastroscopists should appreciate that caution is necessary in the passage of the flexible gastroscope.

"Dead Hand" in Users of Vibrating Tools.—Men in engineering works sometimes use a high speed electrically driven tool with 2,900 revolutions per minute. The worker steadies the tool with the right hand, but the heavy part of the work in guiding and holding the tool is done by the left hand, which is the first and usually the only hand to be affected by vascular disturbances. The number of workers who have reported vascular disturbances in the hands is 75 out of 300 who use this high speed tool. Telford and his associates have made a detailed study of 34 of these patients. At the onset a sudden blanching and deadness of one or more fingers occurs. After a variable interval the white stage gives way to a deep leaden cyanosis. Later the cyanotic area becomes mottled with salmon colored patches, which gradually increase and coalesce, leaving the fingers for a time redder than normal. The length of an attack may vary from a few minutes to several hours. If the patient dips his hands in tepid water or brings his body into warmer surroundings, the duration of the attack is considerably reduced. The chief trouble is the loss of sensation and uselessness of the hand during an attack, which causes serious disability. The condition is likely to persist after the man has given up the work. There was no evidence that excessive smoking caused a predisposition to the disease. X-ray examination of the hands of 21 patients did not reveal calcinosis, ulcers of the pulp or acrosclerosis. The rate of revolution and the hardness of the metal are important factors. With soft or heated metal—e. g. hot rivets—and with a speed under 2,000 revolutions per minute the risk is probably insignificant. The use of gloves or rubber pads is not satisfactory because they interfere with accurate control of the tool. An attempt has been made to damp out the vibrations by sheathing the tool in a sleeve of gas mask tubing. This method seems to have possibilities. The working of shorter hours has been suggested, but the result of this probably would be merely to postpone the onset of the disease. It is suggested that workers should not be employed on this type of work for more than nine months. The medical treatment of the condition is unsatisfactory. The most useful advice is to avoid cold to body and hands alike. This is not easy for most workers and is impossible for those in outdoor occupations.

Tissue Changes Induced by Clostridium Welchi Filtrates.—Robb-Smith uses the term gas gangrene in the sense of a clostridial myositis associated with severe constitutional symptoms. There is a preservation of myofibrils but disruption of the sarcolemma and fragmentation of the muscle fibers. The fibers are separated by an edema of the endomysial connective tissue, the reticulin membrane of the muscle fiber is separated from the sarcolemma, and there is partial to complete destruction of reticulin fibrils and collagen fibers, but the elastic fibers are unaffected. There is nuclear karyolysis and the appearance of extracellular fatty droplets, while fat cells show a breakdown to fatty acid crystals. There is no vascular hyperemia, little fibrin formation and no neutrophil cellular reaction; leukocytes in the vicinity of a lesion undergo karyolysis and cytolysis. Comparing these lesions with the changes occurring in human muscle in vitro from the action of Clostridium welchi type A filtrate the author says that they are morphologically identical save for the absence of edema or gas formation. An attempt has been made to analyze these changes in terms of the action of the enzymes known or suspected to be present in the filtrate, and it appears that the alterations are due to effects on cell membranes, cell nuclei, collagen and reticulin, and mucoproteins, and that the myofibril is unaffected. The lack of cellular reaction is not due primarily to the ischemia but to the cytolytic action of the filtrate, and since these changes can be inhibited by antitoxin it is suggested that local injection of antitoxin might be used where it has proved impossible to perform an adequate surgical excision of the affected tissue.

Damaged Intervertebral Disk.—Crisp states that clinically cases of damaged intervertebral disk are distinguished by extreme and persistent spasm of the lumbar portion of the erector spinae muscle and hamstring spasm of less severity. When the patient stands erect, little abnormal is noted beyond a slight increase in the lumbar curve, but on bending forward to touch the toes lumbar spasm becomes obvious. This is sufficient to prevent forward flexion in the joints of the lumbar spine, for there is movement only at the hip joints and the upper dorsal region. The patient will complain of aching lumbar pain, which is aggravated by movement and coughing and often radiates into the groin. There is tenderness to deep pressure over the sacroiliac joint and the interspinous ligament of the affected segment. The sacroiliac tenderness often develops first; this may explain diagnostic errors. The author treated these cases by complete rest, either in bed or in a plaster jacket. Results in the cases so treated have been satisfactory. The patients have lost their lumbar pain, they have not developed sciatica and they have been discharged from the hospital in six to eight weeks with some residual, but permanent, stiffness of the back. Cases which escape diagnosis until after the onset of sciatic pain may be divided into two groups, depending on whether the annulus fibrosus is partially or completely ruptured. The former group may be recognized by the fixed lumbar lordosis, the latter by the fixed lumbar kyphosis. Both groups usually respond well to immobilization in a spinal jacket.

Protrusion of Intervertebral Disks.—Burns and Young analyze the records of 604 patients with low back pain on sciatica. The type of injury or work associated with the majority of these cases has been heavy lifting and falls on the buttocks, which include heavy landings in an airplane and tank driving over uneven country. The most constant characteristic of a disk protrusion is restriction of movement in the anteroposterior plane while lateral movement is free. With increased experience the authors diagnose disk lesions more often. They find it necessary to operate on only about 2 of every 5 patients diagnosed as having a disk lesion. When the symptoms are slight they recommend wearing a belt or corset to restrict the movement of the lumbar spine. If the patient is seen in a first attack he is put to bed. In about half the cases the attack will subside. If after three weeks there has been no improvement, operation is recommended. To persist with rest and immobilization in a plaster bed for many weeks often failed to give relief and was a less acceptable procedure than operation. The authors do not favor the plaster jacket because it is much less comfortable and no more effective than a corset. When operation has been decided on, accurate localization of the lesion is desirable, but unfortunately it is not possible because x-ray films, either plain or with contrast mediums, and neurologic signs are of little help. The great majority of protrusions come from the disks between the fourth and fifth lumbar vertebrae or the fifth lumbar and first sacral. The authors use a free exposure because it gives easier access than the small interligamentous approach or a hemilaminectomy. In 177 laminectomies performed for suspected lesions of the disk, protrusions were found in 141. In 19 of the others intraspinal abnormalities were found. Of the 141 with proved disk lesions 131 were immediately relieved and have remained free from symptoms to date.

Blast Injury of Brain.—Rogers states that structural changes may be produced in the brain or cord of those in the vicinity of an explosion. He reports that a seaman aged 19, after standing close to a 4 inch gun during its discharge, noticed a sudden numbness in the left hand and arm which lasted for about ten minutes. Three weeks later began the first of a series of attacks of numbness and tingling, which, starting in the left hand, spread to the elbow, shoulder and side of the face and were accompanied by involuntary abduction and elevation of the arm, spasm of the face and loss of consciousness for a few minutes. On recovery there was some residual weakness of the left upper extremity, which gradually increased and spread to the leg, and seizures became more frequent, occurring four to six times a day. It was decided to explore the postcentral areas, and a bone flap was turned down in this region. The dura in the posterior part of the field was bulging, and when it was opened the cerebral gyri here were green, widened and elevated over an area about the size of a penny. On incision of the brain in this area a shallow but extensive cavity was entered containing old blood clot. This was removed, and the patient made an uninterrupted recovery; some residual weakness and astereognosis remained. Somewhat similar cases were reported by Mott in the last war, the lesions being discovered at necropsy. It has been suggested that the mechanism responsible for the production of the cerebral lesions is the hydraulic-like pressure transmitted to the cerebrospinal axis in its closed bony walls by sudden compression of the thoracic cage. Such compression must produce violent back pressure on the venous side of the circulation. A sudden rupture of vessel walls may conceivably be caused by the decompression which suddenly succeeds the compression wave.

Penicillin Treatment of Experimental Syphilis.—Bessemans and Derom report the results of treatment of experimental syphilis in rabbits and mice with massive doses of penicillin. Five thousand Oxford units of penicillin was injected intramuscularly at three hour intervals into the rabbits, the total dose amounting to 320,000 units in eight days. Two hundred Oxford units was injected at the same interval and by the same route into mice, with a total dose of 12,800 units in eight days and a total dose of 18,400 units for eleven and a half days. In both groups complete and permanent sterilization from Treponema pallidum was obtained with this treatment, although it was begun two to twelve months after the onset of the disease in rabbits and three to four months after the onset of the infection in mice. Dissection of parts of the brain and of peripheral lymph nodes was performed three to six months after the completion of the penicillin treatment. These results are in contrast to the negative results obtained by Neymann and Youman with penicillin treatment of late syphilis of the central nervous system in man. It is suggested that differences in the anatomic structure and dissimilarity of the minute pathologic process in the central nervous system syphilis of man may be responsible for these contradictory results.

*Treatment of Tuberculosis of Larynx with Procaine Hydrochloride Infiltration of Carotid Sinus. R. LeLourd.—p. 503.

Procaine Hydrochloride Infiltration of Carotid Sinus.—LeLourd practiced procaine hydrochloride infiltration of the carotid sinus in 16 cases of tuberculosis of the larynx with ulceration and intense pain. Good results were obtained in 15 patients with repeated injections of 20 cc. of procaine hydrochloride in 1/200 solution. The disappearance of the sinocarotid reflex (whether or not it is accompanied by Horner's syndrome) demonstrates sufficient infiltration. Pulsations transmitted to the needle demonstrate that the injection is made close to the blood vessel. Infiltration of both carotid sinuses may sometimes be required, although relief from pain is often accomplished almost immediately with unilateral infiltration. Primary ischemia may subside rapidly and be followed by secondary vasodilatation, which may still be manifest on the fifth day. As a rule the effect of the infiltration lasts from five to ten days and not longer than twenty days. Infiltration may be repeated for months without losing its effectiveness. In 3 of LeLourd's cases there was complete relief from pain, disappearance of the edema and cicatrization of the ulcerated area. Although the latter effect will not be obtained frequently, infiltration of the carotid sinus is an excellent method of treatment of tuberculosis of the larynx.

*Paroxysmal Tachycardia in Young Child: Paroxysmal Tachycardia Persisting for Months and Caused by Isolated Interstitial Myocarditis of Right Auricle. A. Piotti.—p. 121.

*The Heart in Training and in Excessive Training. A. Delachaux, M. Mamie and G. Aymon.—p. 173.

Variations in Glycogen and Pyruvic Acid of Heart During Electrocardiographic Modifications Observed in Rats with B Avitaminosis: Role of Pyruvic Acid. J. Van Heerswynghels and J. Thomas. —p. 211.

Paroxysmal Tachycardia in Young Child.—Piotti describes clinical and anatomic studies on a child aged 11 months with atrioventricular paroxysmal tachycardia. The first paroxysm lasted twenty-three days. There was a free interval of three days followed by tachycardia which could not be controlled and which persisted for seven months. At the onset of the disease the electrocardiogram of a normal sinus rhythm exhibited a widened and notched P as a manifestation of myocarditis in the right auricle. After the tachycardia had persisted for seven months the P wave became normal although both auricles were greatly dilated. The ventricular complex remained normal in spite of a tremendous hypertrophy and dilatation of the left side of the heart. Microscopic examination of serial sections of the myocardium revealed an interstitial myocarditis of Fiedler's type. It was located exclusively in the right auricle in the region of the sinus bridge fibers (from the Aschoff-Tawara node to the orifice of the sinus coronarius), whereas the sinus node and the entire atrioventricular system and the remainder of the myocardium was free from inflammation and scars. The pericardium, valvular apparatus, endocardium and vessels were unimpaired. The localization of the myocarditis as demonstrated pathologically was in agreement with the electrocardiographic findings. Inflammation of the upper respiratory tract which had preceded the tachycardia was regarded as the possible etiologic factor. Since interstitial myocarditis may be a localized process, examination of serial sections of the myocardium is essential for proof of the infection. Because of the close connection between the myocardial fiber and nerve termination, a differentiation between myogenic and neurogenic origin is impossible in paroxysmal tachycardia.

The Heart in Physical Training.—Delachaux and his co-workers show that physical training produces a number of changes in the human body. In sports involving great endurance changes occur particularly in the lungs, the circulatory apparatus and the products of cellular respiration. Some of these changes protect the heart against overstrain. In the well trained subject the peripheral resistance of the circulation is diminished by neurovascular regulations, while a denser capillary network and a high intracellular hemin level create optimal conditions for metabolic exchange between blood and cells. Consequently the same amount of cardiac energy will supply more oxygen to the periphery in the trained than in the untrained organism. The heart muscle undergoes changes similar to the skeletal muscle changes. Greater vascularization, increase in cellular hemins (which carry and store oxygen) and increase in respiratory products insure protection against oxygen deficiency during exertion. The heart undergoes hypertrophy and dilatation which involves particularly the length of the heart rather than the transverse diameter. This dilatation enables the heart to deliver a large quantity of blood to the periphery without greatly accelerating its rate. Large "athlete's hearts" are rarely observed; at rest their walls are relaxed and show only mild pulsation. During exertion, however, these hearts contract normally and reduce their volume, expelling their residual blood into the circulation. This type of heart is rare; it represents a highly efficient phenomenon of adaptation to exertion and is peculiar to certain constitutional types; it has no pathologic significance. When intensive training ceases, the cardiac volume decreases gradually. After years of an athletic career, the heart of the well trained athlete may show no clinical change, except perhaps an unusual tolerance for exertion. It is the exception for maximal athletic training to cause heart damage in the initially healthy subject. Systematic examination of a number of overtrained athletes revealed only neurovegetative disturbances, which subsided when excessive training was stopped. The "forced" or overstrained heart is the result of an earlier defect aggravated by the athletic exertion. This defect may have been the result of myocarditis, coronary sclerosis, arterial hypertension, anemia or neurovegetative or endocrine factors.

*Gas Gangrene of Gallbladder: Clinical and Roentgenographic Study. A. Pierini.—p. 988.

Gas Gangrene of Gallbladder.—A woman aged 63 with an acute abdominal condition presented a tumor-like mass palpated in the region of the gallbladder. At the operation, described by Pierini, gangrene of the gallbladder and free bile in the peritoneum were found. Fundal cholecystectomy was done, with drainage of the perforated gallbladder. Sulfanilamide was applied locally. Polyvalent antigangrenous serum and intravenous infusions of a 20 per cent sodium chloride solution were administered. The rest of the gangrenous gallbladder was removed through the operative wound ten days after the operation. Gas bacilli were recovered from the fluid of the putrescent gallbladder. The gas bacilli were identified by cultures and by inoculations of mice and guinea pigs. The bile obtained forty-five days and ninety days after the operation did not contain anaerobic bacteria. The patient recovered.

*Dextrose Solution and Vitamin B_1 in Therapy of Vomiting in Pregnancy. A. Acosta G.—p. 370.

Therapy of Vomiting in Pregnancy.—Acosta G. reports good results in 59 of 60 women with severe vomiting of pregnancy. Treatment consisted in daily intravenous injections of 2 cc. of vitamin B_1 in 20 cc. of a 50 per cent dextrose solution. Vomiting was controlled in the majority of the cases after the second injection. Occasionally, a third injection was necessary. The author believes that vomiting of pregnancy is due to two different factors: (1) a lack of antiprotein ferments in the mother's blood with consequent intoxication of the mother with fetal proteins and (2) B_1 avitaminosis. Dextrose solution stimulates formation of antiprotein ferments in the mother's blood, whereas administration of vitamin B_1 controls the avitaminosis.

*Cystic Hematuric Form of Poliomyelitis. F. Albert, R. J. Abuin Figueroa and M. Blanco.—p. 343.

Hematuria in Poliomyelitis.—Hematuria in poliomyelitis has been previously reported only in the preagonal stage. Albert and his collaborators observed hematuria in several patients during the 1942 epidemic. Patients with hematuria presented also paraplegia of the legs, alone or associated with paresis of the arms. The consequent atrophy of the legs was severe. The patients did not have dysuria or renal or gastrointestinal disorders. The course of the neuromuscular lesions was not influenced by the hematuria. The general condition of patients in the course of the hematuric phase was good. Hematuria as a complication of poliomyelitis occurred within the first month of the disease. The urine was normal except for the presence of blood. Some cases of hematuria were complicated by urinary retention. Catheterization in these cases was not followed by hematuria. Blood pressure was normal. In some cases hematuria reappeared after several days with normal urinary secretion. The prognosis is benign, as hematuria both primary and recurrent disappears spontaneously and without treatment. The authors believe that this form of hematuria depends on a selective localization of the poliomyelitis virus in nervous tissues which elicit a transient neurogenic reaction of the bladder, with consequent hematuria.

Book Notices

American Red Cross First Aid Textbook. Prepared by the American Red Cross for the Instruction of First Aid Classes. Revised edition. Paper. Price, 60 cents. Pp. 254, with 264 illustrations. Philadelphia: Blakiston Company, 1945.

The American Red Cross has made available a completely revised version of its first aid textbook, a work that has circulated in millions of copies. More care and expert attention have gone into the preparation of this book than have ever been accorded any similar work. As stated in the preface, the cooperation of the Committee on Surgery of the Division of Medical Sciences of the National Research Council was secured together with that of experts in some of the other medical specialties. Each of the chapters was carefully reviewed and often rewritten by a physician known for his expert knowledge of the subject. The text when completed was then turned over to the Committee on Information of the Division of Medical Sciences, the chairman of which committee gave it a final reading and again edited it. The rewritten text was then referred to the surgical experts and to the staffs of the Office of the Medical Director and of the First Aid, Water and Safety and Accident Prevention Service of the American Red Cross for further review. All of those who participated in this project are given special acknowledgment by name in the new edition. The book differs in appearance from previous editions principally in improved illustrations, better printing and better typography, especially in the use of italics and boldface for emphasis. There is a good index; the book is substantially bound with staples and a cover of water repellent, though not entirely waterproof, paper. Review questions as to what to do and what not to do at the end of the chapters are extremely useful. This book should be very valuable wherever first aid is taught and as a reference book in homes, schools and industry.

Health Instruction Yearbook 1945. Compiled by Oliver E. Byrd, Ed.D., *Associate Professor of Hygiene, School of Health, Stanford University.* Foreword by Walter H. Brown, M.D., Acting Dean, School of Public Health, University of California, Berkeley. Cloth. Price, $3. Pp. 344. Stanford University, Calif.: Stanford University Press; London: Oxford University Press, 1945.

This is the third yearbook by Professor Byrd. Previous editions have been reviewed in THE JOURNAL as issued. The only serious criticism is one which was made by THE JOURNAL with relation to both the 1944 and 1943 yearbooks, namely that they are badly dated. The title itself and the arrangement of the type lead to the conclusion that this is a yearbook covering 1945. Actually it is a yearbook which appears in the fall of 1945. There must have been at least four months between the completion of editorial work and the appearance of the book. Thus it is to a great extent actually a 1944 yearbook containing little material for 1945 and what little it does contain referring only to the first few months. The book contains 316 articles of varying length. Somewhat less than a page is the average length, though some run to several pages. Beginning with articles in chapter one, under the general title of Health as a Social Accomplishment, the book runs through twenty chapters ending with one on trends and probabilities. It gives a good coverage of the public health field, and the articles in general are well selected, useful, diversified and well abstracted. As is pointed out in the preface to this edition, the successive issues will, within a few years, form a useful reservoir of source material which otherwise would be widely scattered through the literature. This book is so useful that it seems too bad that the author and publishers are obdurate in maintaining their unfortunate and misleading dating. The longer they maintain it, the more difficult it will be to correct.

The Afterglow. By Frank G. Nifong. Fabrikoid. Privately Printed. Pp. 347, with 1 illustration. Columbia, Missouri: Aircraft Press, 1945.

Among the leaders of medicine in Missouri have been the several generations of the Nifong family. Dr. Frank G. Nifong tells the story of the family in this privately published volume. His relationships with medical organizations have been intimate, and he has for years been a leader in medical education and in carrying health to the people of his community. His autobiography is a true reflection of his character and his work.

Photosynthesis and Related Processes. Volume I: Chemistry of Photosynthesis, Chemosynthesis and Related Processes in Vitro and in Vivo. By Eugene I. Rabinowitch, Research Associate, Solar Energy Conversion Research Project, Massachusetts Institute of Technology, Cambridge, Massachusetts. Cloth. Price, $8.50. Pp. 599, with 63 illustrations. New York: Interscience Publishers, Inc., 1945.

The "most important of all biological processes," as the author designates photosynthesis, was last reviewed in 1926. Volume I of this present planned two volume work contains largely chemical material, together with a brief review of early important research work, and is divided into part I, on the chemistry of photosynthesis and related processes, and part II, on the structure and chemistry of the photosynthetic apparatus. Since the preceding review, twenty years ago, several new avenues of approach to the problem of photosynthesis have been developed, such as oxygen liberation by isolated chloroplasts, synthesis in bacteria, the effect in certain algae of substituting new substrates for carbon dioxide and water, the use of flashing light, feeding isotopes such as heavy hydrogen, studies in fluorescence of living plants, use of the electron microscope and numerous other new biochemical and physical methods not peculiar to this particular problem. This well written comprehensive monograph contains numerous equations, tables, charts and diagrams. At the end of each chapter a bibliography is arranged in chronological order dating back to work as early as 1776. A valuable author index to the volume lists also the contribution of each scientific worker.

Handbook of Physiology and Biochemistry: Originally "Kirkes'" and Later "Halliburton's." By R. J. S. McDowall, M.D., D.Sc., M.R.C.P., Professor of Physiology, University of London, King's College, London. Thirty-Eight Edition. Cloth. Price, $6. Pp. 898, with 305 illustrations. Philadelphia: Blakiston Company; Edinburgh: Oliver & Boyd, Ltd., 1944.

The thirty-eighth edition of any book deserves comment. The volume under review was originally (1848) the work of William S. Kirkes and later of a number of authors until 1896, when Professor Halliburton became its responsible writer. In 1928 R. J. S. McDowall assumed charge, and the current edition represents his work. This book apparently owes its long life and perennial success to the fact that it presents the basic subject matter of physiology in a simple, direct and fairly complete way. The present edition introduces considerable biochemistry and retains a good deal of gross and microscopic anatomy. It is printed on "wartime paper," but otherwise the mechanical aspects of the book are satisfactory. Interest in it will probably be limited to beginning students, because it is not well documented and it fails to present much of the more recent contributions to knowledge in physiology.

The Dice of Destiny: An Introduction to Human Heredity and Racial Variations. By *David C. Rife, Ph.D., Associate Professor of Zoology,* Ohio State University, Columbus, Ohio. Cloth. Price, $1.75. Pp. 163, with 23 illustrations. *Columbus: Long's College Book Company,* 1945.

The figurative title of this book masks a work for the public on heredity. By the dice of destiny the author means the genes which determine inheritance of both physical and mental qualities. The author discusses the blood groups, the inheritance of physical traits, twins, mental capacity, personality and similar subjects. A final chapter on the genes and democracy emphasizes the view of the author that education of the heart is essential for human security. Intellectual education and scientific achievements will give us a better world in which people will live joyfully if men are motivated by the spirit of brotherly love.

Recent Advances in Neurology and Neuropsychiatry. By W. Russell Brain, M.A., D.M., F.R.C.P., Physician to the London Hospital, London, and E. B. Strauss, M.A., D.M., F.R.C.P., Physician for Psychological Medicine, St. Bartholomew's Hospital, London. Fifth edition. Fabrikoid. Price. $5. Pp. 363, with 32 illustrations. Philadelphia: Blakiston Company, 1945.

This is one of the most practical and popular treatises on recent advances in neurology. It should be in the hands of every general practitioner, neuropsychiatrist and neurosurgeon. It presents new facts on electric shock therapy in mental diseases, a discussion of prefrontal leukotomy, peripheral nerve injuries, vascular changes after chilling, a syndrome of neuritis of the shoulder girdle, the use of penicillin and an ample discussion of electroencephalography. It is extremely up to date, is well written and is highly recommended.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

CLIMATE AND SINUSITIS

To the Editor:—A patient has chronic sinusitis and wishes to move to some point in the United States where he might obtain some relief. Would you send any available information as to favorable climates or locations.

Martin J. Rosten, M.D., Silver Creek, N. Y.

Answer.—The ideal and therefore most favorable climate would be the one in which there would be the least variability between the morning and evening temperatures (not less than 68 F. nor more than 75 F.), normal relationship between temperature and humidity, and finally just sufficient velocity of the wind to impart "life" to the air, thus giving one a sense of well-being.

This ideal can rarely be realized, but there are a number of locations that might approach it. Florida, southern California or perhaps Arizona should be seriously considered. If the patient is free of allergy, he could take a vacation in one of these areas. It is of the utmost importance to remember that the patient will have to allow time to accustom himself to the new atmospheric environment before any conclusions can be drawn. If, after a sufficient time has elapsed, the patient has not improved, another climate might be tried.

The value of favorable climates does not rest on any curative power in the air per se but on the fact that the patient is away from his former environment and is not now subjected to the inclemencies of weather with sudden changes in temperature, humidity and wind velocity.

All climatologists feel that no one climate can be suitable for all persons; hence the necessity for attempting to determine whether any given location is favorable or unfavorable.

RESUSCITATION OF NEWBORN INFANTS WITH ALPHA-LOBELINE

To the Editor:—Alpha-lobeline has been used in the obstetric department in the Pierce County Hospital, Tacoma, Wash., for the resuscitation of infants with asphyxia neonatorum. The use of this product has become routine and the value of the drug has been accepted without any question or without any skepticism. However, my knowledge of the drug Lobelia, remembering that it belongs to the tobacco family, caused me to question the alleged efficiency of the drug as claimed by the pharmaceutical firm that markets it. We recently lost an infant born by cesarean section in a case of actively bleeding placenta previa. The child lived for about seven hours. The trachea was freed of mucus by aspiration through a catheter and oxygen inhalations were given prior to the administration of the alpha-lobeline. Some authorities state that the drug, within one-half hour or so, is followed by symptoms of depression of respiration. The information that I desire is this: Are we warranted at all in using this drug for this purpose and am I, as superintendent, warranted in forbidding its use within the hospital and if so, on what grounds?

Burton A. Brown, M.D., Tacoma, Wash.

Answer.—The Council on Pharmacy and Chemistry issued a preliminary adverse report on alpha-lobeline in 1927 (The Journal, Aug. 27, 1927, p. 693) and a report of rejection in 1933 (June 17, 1933, p. 1933). The pharmacologic investigation of Norris and Weiss (*J. Pharmacol. & Exper. Therap.* **31**:43 [May] 1927) had shown that the pharmacologic properties of alpha-lobeline are essentially the same as those of the amorphous impure alkaloid or of extracts of the lobelia inflata, that the emetic, respiratory and vasomotor actions of alpha-lobeline are similar to those of nicotine and that carbon dioxide and oxygen mixture is a more efficient and safer respiratory stimulant than alpha-lobeline. These conclusions have been confirmed by further experience. Goodman and Gilman (The Pharmacological Basis of Therapeutics, New York, Macmillan Company, 1941, p. 495) state that "the early enthusiastic reports on the value of lobeline as a respiratory stimulant and analeptic have not been substantiated and the drug is too dangerous and uncertain in action to warrant its employment in preference to more effective and safe therapeutic agents." Sollmann (A Manual of Pharmacology, Philadelphia, W. B. Saunders Company, 1942, p. 441) concludes, tersely, "safe doses are not reliable and effective doses are not safe." Clinically, the stimulation is often complicated by nausea and vomiting, sometimes with severe collapse and Cheyne-Stokes respiration. Current textbooks of obstetrics also reflect a negative attitude toward its used. De Lee (Principles and Practice of Obstetrics, Philadelphia, W. B. Saunders Company, 1938, p. 920) gives a tempered approval: "Lobeline hydrochloride is a valuable addition to our remedies. It is used to inaugurate the initial respiration or stimulate flagging ones. . . . The result is sometimes dramatic, the baby gets rigid, then gives a deep gasp. Its effects last only a few minutes." Adair (Obstetrics and Gynecology, Philadelphia, Lea & Febiger, 1940) states that a series of drugs which includes alpha-lobeline "have all proved uncertain in their effects." Stauder (Williams Obstetrics, New York, Appleton-Century Company, 1940, p. 1110) writes "Alpha-lobeline has been suggested in the treatment of asphyxia neonatorum. Its effect as a respiratory stimulant is open to question." Titus (The Management of Obstetric Difficulties, St. Louis, C. V. Mosby Company, 1945, p. 894) reports that the advisability of using such drugs has been so questioned by Cole that the propriety of their use is decidedly questionable. He says their use as a stimulus to respiration is immediately followed by a corresponding or even greater depression. Beck (Obstetrical Practice, Baltimore, Williams & Wilkins Company, 1942), Davis (Gynecology and Obstetrics, Hagerstown, Md., W. F. Prior Company, 1934) and Schumann (Textbook of Obstetrics, Philadelphia, W. B. Saunders Company, 1936) do not even mention alpha-lobeline in the treatment of asphyxia.

These citations bear out the conclusion that alpha-lobeline is a potent but uncertain and always dangerous drug, without material advantage over the safer and equally or more effective measures that are now generally employed for resuscitation.

HAZARDS FROM PHENOTHIAZINE

To the Editor:—Does phenothiazine, used as anthelmintic in livestock, have any deleterious effects on persons who work with it a great deal? What damage may they suffer? Are the effects cumulative?

A. I. Arneson, M.D., Morris, Minn.

Answer.—Photosensitization may result from the absorption of phenothiazine, and exposure to sunlight then produces a dermatitis. This has been reported in orchard workers using the insecticide in sprays. Symptoms include intense itching, irritation and reddening of the skin, sometimes with edema and secondary infection. The agent is absorbed only through the alimentary or respiratory tract, and not through the skin, and for this reason the wearing of a protective mask by exposed workers has been suggested. Also of value is the avoidance of sunlight by protective clothing or ointments.

Except for photosensitization, the hazard is slight. As a urinary tract antiseptic, nearly 100 Gm. in four months has been taken without deleterious effect by some persons, but in others a secondary anemia has been produced. This has led to the suggestion that actual systemic therapy with the drug be limited to courses in which the total dosage is less than 15 Gm. Undesirable effects could not be demonstrated on the gastrointestinal tract, circulation, kidneys or liver of man or experimental animals.

EMBOLISM, HYPOPROTHROMBINEMIA AND OBSTRUCTIVE JAUNDICE

To the Editor:—I wish to know if there are any studies of statistical significance comparing the incidence of pulmonary embolism in the postoperative course in patients with obstructive jaundice against those without jaundice. These figures should be for the period before the advent of vitamin K. Such studies might throw a clearer light on the rationale of using dicumarol for prevention of pulmonary embolus in thrombophlebitis and phlebothrombosis.

Captain, M. C., A. U. S.

Answer.—The query is obviously directed toward the influence of the hypoprothrombinemia in obstructive jaundice on postoperative thromboembolism. Statistics which would indicate a lessened incidence of postoperative thrombosis in patients with obstructive jaundice as compared to a similar group of patients without jaundice are not available. Their value, however, would be questionable, since it is known that many patients with obstructive jaundice have a normal concentration of prothrombin (Quick, A. J.: Stanley-Brown, Margaret, and Bancroft, F. W.: *Am. J. M. Sc.* **190**:501 [Oct.] 1935. Rhoads, J. E.:

Surgery **5**:794 [May] 1939. Pohle, F. J., and Stewart, J. K.: *J. Clin. Investigation* **19**:365 [March] 1940). These authors and some others have indicated that the hypoprothrombinemia is not proportional either to the intensity or to the duration of the jaundice. Also since the hemorrhagic level of prothrombin is below 20 per cent of the normal, many patients with jaundice have small reductions which would not necessarily protect them from postoperative clotting. The question of the correspondent, however, opens up another problem. Does a high grade hypoprothrombinemia in man really prohibit the occurrence of clotting? Some patients with advanced cirrhosis of the liver and with ulcerative colitis exhibit a severe hypoprothrombinemia, in spite of which thrombosis developed in the calf muscles. While prothrombin is an important factor in the process of clotting, this mechanism may still operate in the presence of diminished quantities of prothrombin.

DIAGNOSIS OF ALLERGIC RHINITIS

To the Editor:—A woman has had hay fever-like symptoms for a few years in succession about the middle of August. She is affected only at night when it gets colder outside and invariably feels better during the day, especially when it is sunny. She was tested by scratch and injection method both by a good allergist and by me and does not respond to hay fever. She has a lot of hydrangeas (snowballs) around her summer home in Peekskill, N. Y., and they are blooming now. Could the hydrangeas be the cause? Should she be tested with other pollens growing in that locality? I want to stress again the point that she feels better during the day, which would seemingly eliminate pollen as the cause of this condition. Besides having rhinitis she also has aches in the limbs and body as present usually in grip.

M.D., New York.

Answer.—To diagnose this condition properly one must make a complete investigation not only of the patient but of the patient's environment. Pollen sensitivity cannot be definitely ruled out despite the inquirer's statement that "the patient does not react to hay fever." There are patients encountered occasionally who have negative skin reactions with ragweed pollen or who react only when examined with concentrated ragweed solution intradermally but whose symptoms are nevertheless due to ragweeds. In addition, other pollens and other inhalant materials present primarily during August (lamb's quarter, for example) should be considered. There is also the possibility of exposure to an excessive amount of molds during August and September because of local conditions around the patient's home. Other inhalant allergens peculiar to the vicinity of the patient's home or to the home itself may contribute to symptoms only during this season.

Regarding the question of the possibility of hydrangeas being the cause of the patient's trouble, that, while not impossible, is a very unlikely assumption. The patient would have to be within a few feet of the hydrangeas or would have to have her house or her room profusely filled with these flowers to have symptoms from them.

PENICILLIN FOR CHRONIC TONSILLITIS

To the Editor:—Can penicillin be used in the treatment of chronic tonsillitis?

Hyman Sherman, M.D., Brooklyn.

Answer.—It would be best perhaps to define what is meant by chronic tonsillitis. If by the term is meant enlarged tonsils or chronically reddened ones or tonsils with crypts containing caseous plugs, then the use of penicillin is apt to be without effect. If by chronic tonsillitis is meant one of these plus acute flare-ups characterized by sore throat, increased redness or fever, penicillin during these exacerbations may be of considerable benefit. There is not much likelihood, however, that the use of penicillin can restore a hypertrophied or a chronically infected tonsil to a normal condition or that it will favorably affect the presence of caseous plugs. In using penicillin repeatedly for conditions not apt to be improved by its use such as described, it should be borne in mind that the patient may develop a more serious condition later that may be penicillin resistant. Hence penicillin ought not to be used for trivial infections.

AIR DISINFECTION IN HOSPITALS

To the Editor:—Are any of the methods of air sterilization recommended for general use in hospitals and nurseries?

Martha O'Malley, M.D., Boston.

Answer.—Treatment of floors and bedclothes with oil emulsions to hold down infected particles of dust and lint has proved of sufficient value in military barracks and station hospitals to recommend trial in civilian hospitals. Other methods of air disinfection are still in the experimental stage. High intensity ultraviolet irradiation is fairly effective against droplet nuclei, but its use at present is limited by harmful effects on the eyes and skin. There is not good evidence that glycol aerosols accomplish much under practical conditions of room occupancy. The use of antiseptic mists is also limited by toxicity, odor or corrosiveness to metals and clothing.

IMPAIRED VISION FOLLOWING MEALS

To the Editor:—Frequently I find that patients have impaired vision following a meal; their vision is hazy. Could this be due to an increase in blood sugar? During the past twenty-five years many of my patients with diabetes have complained of impaired vision, especially when the blood sugar is high.

William V. Vandervoort, M.D., Battle Creek, Mich.

Answer.—So far as the increase in blood sugar following a meal is concerned, evidence is not readily available to substantiate the theory that impaired vision is caused thereby. According to Adler the retina rapidly utilizes sugar, and the retina "splits" much more sugar than does any other tissue. Many observers have reported alterations in the refractive power of the eye in patients with diabetes which probably vary with the sugar content of the blood. Certain observers have stated that this variation is as much as 5 diopters. It is also known that an autotoxemic amblyopia may be associated with diabetes. Some patients with visual complaints difficult to attribute to a specific cause have circulatory and toxic disturbances which probably affect their vision. There is a possibility that, after drinking tea or coffee with a meal, contraction of the retinal vessels might impair vision in certain persons with a tendency to vasospasm. Patients with impaired vision following a meal might have an allergy to certain foods.

DIABETES AND LYMPHATIC LEUKEMIA

To the Editor:—A man aged 67 has had diabetes mellitus for twelve years, during which time he has taken insulin daily in doses up to 60 units; he has also been on a high fat, low carbohydrate diet. About six months ago a diagnosis of chronic lymphatic leukemia was made, and at the same time the amount of sugar in his urine began to drop and the required dosage of insulin was gradually diminished until at present he is taking 15 units every second or third day. At the same time he has been able to increase his carbohydrate intake. Is there any physiologic explanation?

Carlos E. Kemper, M.D., Viborg, S. D.

Answer.—Is the improvement in the diabetes not due to the advent and advance of the lymphatic leukemia, which may have resulted in less intake of food and consequent reduction in weight? Such a condition is sometimes seen in tuberculosis and cancer, particularly if the latter involves the liver. Lymphatic leukemia is rare in diabetes and diabetes rare in lymphatic leukemia, as found by consultation of the literature of both diseases and by the personal interrogation of physicians concerned in their treatment.

ENLARGED SPLEEN AND MALARIA

To the Editor:—A young man suffered an attack of acute infectious mononucleosis fifteen years ago and his spleen has remained enlarged, one and a half fingerbreadths below the margin of the ribs, ever since. He has otherwise been in excellent health with normal blood count. Should this young man for some reason or other go to some tropical country where he may acquire malaria or some other tropical disease affecting the spleen, would he be running a greater than average risk of succumbing to the infection?

M.D., New York.

Answer.—Enlargement of the spleen as a result of an acute infectious mononucleosis does not alter susceptibility to malaria. If the man is contemplating travel or employment in a tropical area, the fact that there is an enlarged spleen should not influence his decision particularly as far as malaria is concerned.

INHIBITING EFFECTS OF AUTOLYZED BACTERIA ACTION OF PENICILLIN

To the Editor:—The effect of sulfonamides is known to be eventually diminished by an inhibitor substance, para-aminobenzoic acid, liberated from autolyzed bacteria. I wonder whether anything similar might happen while using penicillin. Is there anything known about that subject?

M.D., Bolivia.

Answer.—There is nothing known about the inhibiting effect of autolyzed bacteria on the action of penicillin except in the case of the colon bacillus. Extracts of Escherichia coli are capable of inactivating penicillin in vitro. There is no evidence that this phenomenon is operative in the treatment of human infections.

SHOCK AND REFRIGERATION

LYMAN WEEKS CROSSMAN, M.D.
and
FREDERICK M. ALLEN, M.D.
New York

In war, problems of shock and trauma attain even more than their usual importance. A more general understanding of the newer ideas and methods may sometimes improve therapeutic results.

In 1939 Allen[1] proposed the theory of a dual mechanism in shock. The physical factor is evident in cases in which the edema of injured tissues withdraws sufficient fluid from the circulation to account for death, without an assumption of a toxic factor. On the other hand, severe shock can be fatal with a smaller local fluid extravasation, and the toxic explanation seems obligatory when death occurs after injections of plasma or other fluid have maintained an adequate circulatory volume at all stages. The desired direct proof of the toxic hypothesis has been furnished in the demonstration by the Chambers group[2] of circulating substances with vasoexcitor or depressor properties corresponding to the different stages of shock. The variable picture of shock may therefore be partly accounted for by varying proportions of these two factors in different cases, and the response to treatment may perhaps vary accordingly. The physical factor forms the basis of the prevailing treatments of shock, in which the fluid migration is compensated by fluid administration or, when possible, prevented by local pressure.

The first world war gave origin to the theory that fluid replacement must be in the form of plasma or an equivalent colloid solution and that crystalloid injections are harmful because of flushing additional plasma protein out of the circulation. Davidson and Underhill[3] having made no comparisons of the benefits of saline solution and plasma, the first contradiction of the universally accepted doctrine was furnished by animal experiments[1] proving isotonic solution of sodium chloride to be equal or superior to plasma for shock. This result was confirmed by some writers[4] but disputed by others, chiefly because of deficiencies in quantity or timing of injections or hemorrhagic or other complications in their experiments.[5] Using standardized burns in mice, Rosenthal[6] furnished convincing proof of the equal efficacy of plasma and equivalent quantities of sodium salts in noncolloid solution, also of plasma or serum administered by vein, stomach or peritoneum. Fox,[7] following and confirming Rosenthal, contributed analyses showing the origin of the protein of exudates to be from breakdown of injured local tissues, thus disproving the supposed essential role of plasma proteins.

The points of superiority of isotonic solution of sodium chloride over plasma, as stated by Allen,[1] are that it is more conveniently and abundantly available, is tolerated safely in larger quantities and passes most readily into the tissues to supply their specific need for fluid and salt. After six years this view has been accepted in an official memorandum,[8] which prescribes treatment of burns with larger volumes of fluid than could be supplied with due rapidity in the form of plasma even if it were available. The attempt, however, to distinguish the small fraction of fluid given in the form of plasma as serving "to restore blood volume and to treat shock" appears as an indefensible relic of the colloid theory. There was no difficulty in maintaining blood volume with salt solution in shock or burns.[9] Since the specific physical process in shock is the edema and exudation in injured regions, as just explained, the large volume of salt solution which supplies this need is the specific shock treatment. Also the latter half of the quotation implies that the only specific virtue for shock treatment is contained in the small amount of plasma protein, which is now known to be untrue. This wrong theory can sometimes lead to fatal results in practice, because the administration of plasma as emergency treatment in the critical collapse stage is encouraged, whereas the first disproof[10] of the doctrine of irreversibility of advanced shock was accompanied by the demonstration of better recovery with saline solution than with plasma in dogs dying from either tourniquet shock or burns.

Though ranking all sodium salts essentially on a par, Rosenthal and Fox gave a slight preference to the lactate especially as being least nauseating for oral administration. Among the errors of other authors

are comparisons only of equal volumes of plasma and various salt solutions, whereas therapeutic instructiveness consists in comparing the optimal results obtainable with each material. Using the least complicated forms of shock and optimal quantities and timing, the results with plain saline solution were found superior[1] to the best obtainable with pure plasma, and the later claims of improvement by additions of bicarbonate, succinate, fumarate and so on constitute an interesting but unsettled question, owing to differences in methods.

Parenteral injections of nutrient substances may be helpful in the postshock period, but their general use during the shock crisis should be condemned. In rare instances of extreme malnutrition or desiccation a solution of glucose in water may supply food and fluid without contributing to a possibly dangerous excess of salt; but in advanced shock there is danger of increasing mortality by dilution of the vital electrolytes.[11] Also in average patients with shock of such severity as to preclude mouth feeding, the frequent advice to improve strength or assist liver function by adding glucose or amino acids to the saline injections implies an inadequate grasp of metabolic laws. Glucose excites a moderate and amino acids a pronounced rise of metabolism, entailing an increased tissue demand for oxygen in a condition in which anoxia is the chief danger and the blood is already loaded with products of incomplete combustion of these same substances. Such a patient needs a fall of metabolism to a minimum fasting level, the principle being the same as in the reduced temperature treatment.

The converse to fluid administration, introduced by Patey and Robertson[12] in England in 1941, consists in reduction of exudation by pressure of casts or elastic bandages applied to a local region from which shock originates. Benefits to the extent of saving life may be accomplished by this and by the corresponding method of chemical sealing or mechanical compression of burns. These methods have been so widely adopted and rightly approved that only a brief mention is necessary of incidental disadvantages, such as the pressure necrosis of poorly nourished tissues and incubation of bacteria by warmth and moisture. These defects have required modifications of the treatment of burns, and they may receive notice in the course of further experience with limb trauma.

The demonstration of the inhibition of shock by reduced temperature[1] was the first break in the universal tradition of warming shocked patients or their injured parts. The subsequent confirmations, cited elsewhere,[5] are so numerous and harmonious that the briefest summary may suffice here.

The treatment of shock by reduction of the general body temperature was originated by Temple Fay[13] in clinical observations begun in 1940 and first reported in a panel discussion in 1942. Though this report mentions extreme reductions of rectal temperature to about 90 F., the original case records show more frequently 94 to 96 F., and the latter represent the probable ideal temperatures according to the most recent animal experiments. The method is precisely opposite to the tradition of blankets, hot water bottles and electric light cradles. Light covers or mild cooling are used according to the environmental temperature. The rationale is clear, namely the reduction of exudation and probably of toxin formation, the more liberal blood supply to vital organs by constriction of superficial vessels, and especially the relief of anoxia by reduction of total metabolism. Therefore the cooling merely sustains or assists the slight hypothermia which is part of the natural reaction to shock, and it stops short of discomfort and especially shivering, which increase metabolism and aggravate shock. Both clinical and experimental observations now leave no doubt that the difference between high and low environmental or bodily temperatures can amount to the difference between life and death in shock.

The more radical refrigeration which can be applied to local regions has correspondingly powerful effects. It prevents pain and primary shock and thus can serve for operative anesthesia. Also, by temporarily arresting all local metabolism, it inhibits secondary shock and all local reactions to injury. Besides the reduction of the physical factor of exudation, there is halting of production and great diminution of absorption of all kinds of toxins, so that hypothermia is the only known treatment which can affect the toxic factor in shock. There is agreement in recent literature that these effects are sufficient to save life in suitable cases. In addition, the reduced temperature can augment the benefits and remedy the defects of the pressure treatment. Alone or combined with pressure, the cooling may range from near freezing in a crisis to the moderate degree obtainable by the wetting of thin dressings with water or alcohol or exposure to cool air or a fan current. There is no excuse for elevation of temperature in any shock treatment, and the need for cooling is increased by hot weather or a febrile complication.

The action of cold is unique in inhibiting not only pain, edema and shock but also tissue devitalization, infection and intoxication. The treatment therefore continues to find wider uses for conditions which frequently include shock but also emphasize these other properties.

The first clinical use, namely for operative anesthesia, was described[14] in 1937 but did not receive a large scale trial[15] until 1941. The reduction of mortality in poor risk amputation cases by avoidance of shock and various complications has become familiar through many independent reports. A few misapprehensions may be corrected by a reminder that prevention of hypotension by special measures during spinal or other anesthesia has no influence on secondary shock and that a shockless thigh amputation is impossible except under refrigeration. The ability of patients to enjoy full meals immediately before and after refrigeration operations is a small illustration of the difference from other methods. The exceptionally low mortality statistics of a few operators are prima facie proof that their class of patients were strong enough to withstand shock; and if they find reasons for preferring other anesthetics under these conditions, at least the saving of many formerly "inoperable" cases by refrigeration is now established by sufficient testimony.

A form of benefit which nobody has questioned is the checking of intoxication in infected gangrene. When operation must be deferred because of a moribund condition, refusal of consent or other causes, the simple packing of such an arteriosclerotic limb in ice often transforms the condition dramatically within one or two days. The gangrene itself is kept temporarily stationary but is never cured by refrigeration. The respite gained for improving strength may amount to several days or several weeks, but ultimately pain and progressive necrosis return. If permission for amputation is assured, a still more absolute control is obtained by a permanent tourniquet or by McElvenny's[16] plan of solid freezing in preparation for amputation at a higher level.

Closely related to this is the control of dangerous infections in limbs without arteriosclerosis. There is evidence that the chilling extends deeply enough to produce considerable effects on bacterial activity and toxic absorption, even without a tourniquet. The latter should be used in cases of expected amputation but not otherwise, and it should remain in place until after the amputation. The ice pack should extend all the way to the axilla or groin, to control invisible extensions of infection above the tourniquet. With or without a tourniquet, the purpose is usually a temporary arrest of an overwhelming invasion, affording an interval for building up resistance or for serum or other treatments. The most important infection of this class is gas gangrene, and here an added specific benefit seems promised by the high oxygenation of refrigerated blood and tissues, which should be particularly inimical to anaerobes, together with the control of pain, necrosis, bacterial multiplication and toxic absorption. Successful cases were known first to Temple Fay and later ones have been known to ourselves. The report by Ferguson[17] furnishes an example in naval service, and publication of other cases is expected.

Embolism of limb arteries has been treated with refrigeration only at a late stage in order to avert impending gangrene when weakness or cardiac or other complications contraindicated immediate operation.[18] Such a respite for as long as several weeks has sometimes been followed by successful amputation. The longest record was that of a woman who positively refused operation for six weeks and then died of coronary thrombosis, but usually a modified necrosis and intoxication supervene somewhat earlier in spite of the continuous packing in ice or bare ice bags. There has not been an opportunity to try refrigeration in the most favorable early stage.[19] As soon as complete blocking of a major limb artery is established, there can be no doubt of the harmfulness of heat and the benefit of cold. A very small proportion of such cases actually come to operation within the ideal period. It is a simple matter to have such a limb surrounded with ice, even on telephoned instructions. Whenever feasible, a tight tourniquet should be added, well above the arterial obstruction. The cold acts to control pain, preserve tissues and blood vessels and prevent further thrombosis and adhesion of thrombi. The tourniquet intensifies these effects, stops inadequate and injurious collateral circulation, halts the dangerous proximal extension of the thrombus and prepares for operation without other anesthesia. In this way the favorable period for embolectomy may conceivably be extended to a day or two and the results improved. Since postoperative warming in the hope of vasodilatation conduces to both thrombosis and necrosis, not always controllable by heparin, any warming should be kept proximal to the embolic region, and the distal part should be cooled moderately for a day or two.

This proposed use for fresh embolism is closely paralleled by the experiences with trauma, often including thrombosis. The usual purpose is the immediate control of pain and shock and the prevention of infection and necrosis for a long enough time to permit of other needed treatments and recovery. The first outstanding example was McElvenny's[20] case of a man moribund after amputation of both legs by a railway train, who by packing of the stumps in ice was enabled to respond to restorative measures and undergo successful operation after fifty-eight hours, the mangled tissues remaining perfectly fresh. Bowers[21] described arrest of gangrene in traumatic thrombosis cases in soldiers. The highest severity is represented in Mock's[22] cases of fractured pelvis with thrombosis of the iliac or femoral arteries, gangrene being prevented by refrigerating the legs for two or two and one-half weeks. In 1 case with complications of cerebral concussion, severe chest injury, ruptured urethra, infected large hematoma of the buttocks, pneumonia and empyema with rupture into a bronchus requiring emergency tracheotomy and subsequent rib resection, the recovery may be called unprecedented and there can be no question of the conclusion that an earlier thigh amputation would have been fatal. The longest record of preservation is the case of Ottaway and Foote[23] of a seaman on a destroyer, whose femoral artery and vein were severed by a shell fragment 6 cm. below Poupart's ligament and who was kept in good condition by refrigeration of the leg until amputation could be performed one month later. In all these reports it is made clear that amputation was successful far within the area of refrigeration, and a longer stump was saved than would have been possible in an emergency operation. The most important therapeutic principle established, however, is that with dangerous shock present or impending there should be no amputation, débridement or other limb operation that will add to the shock, since postponement is made safe by refrigeration.

The conservative value of refrigeration is shown in observations by I. W. Nachlas[24] of Baltimore, such as the following: A blast accident inflicted serious abdominal injuries, tore off one hand and mangled the other. Because of the severe degree of shock and the traumatism to the abdominal contents, immediate amputations might have been fatal. The stumps were packed in ice for two and one-half weeks before the general condition warranted reconstructive surgery. Then the amputation of one wrist was completed and the numerous fractures and lacerations of the other hand were repaired, the tissues appearing fresh and sound, with the result that the man can go through life with one hand nearly normal in function instead of "the horror of no prehensile limb."

Amputated parts can be preserved in the manner that has long been known for tissues in an ice box. An example of minor use in common daily practice was seen by one of us (L. W. C.) in a case of accidental amputation of the terminal phalanx of a man's thumb, the severed part hanging only by a shred of skin. Distance prevented surgical care for four hours, but meanwhile on telephoned instructions the hand was kept in iced saline solution. Suturing then was followed by healing. The most extreme illustration is the experimental amputation of dogs' legs by Blakemore and his co-workers,[25] the preservation of the legs in a refrigerator for twenty-four hours and their final surgical restoration in position and function. All the reports in the several preceding paragraphs furnish a sufficient answer to the occasionally expressed fear that tissues may be damaged by refrigeration for brief periods, with or without circulation. The exquisitely perfect preservation demonstrated by the Blakemore group, who were unacquainted with Allen's original preservation experiments, furnishes the most complete confirmation of these experiments and disproof of the injurious effect which has been deduced from Brooks and Duncan's experiments.[26]

[24] Nachlas, I. W.: Personal communication to the authors.

The so-called crush injury has received most study in England, where refrigeration has become part of the routine treatment. A tourniquet should be used only if operation is contemplated. In addition to ordinary shock, the existence of a special toxin in such cases is recognized. Cold (with or without pressure) can assist in reducing pain and edema, preserving endangered tissues and restraining infection, besides serving as a shockless operative anesthetic when necessary.

The vasoconstrictor influence of cold is sometimes feared in connection with the occasional arterial spasm in these and other forms of trauma. Nerve blocking with procaine does not always release the supposed reflex. Since refrigeration anesthetizes both nerves and protoplasm, it should theoretically release arterial spasm even when procaine fails.[27] Evidence is the noticeably full blood flow in stumps after ordinary amputations under refrigeration.

The fact that the necrosis following severe freezing is secondary to thrombosis rather than a direct killing effect of cold is the basis of a new treatment [28] in which heparin administration for three or four days brings about healing instead of sloughing. It may be necessary to thaw frozen parts to only a few degrees above freezing in order to prevent both thrombosis and necrosis in the interval before heparin can be obtained. In other respects the use of prolonged moderate cooling remains as part of the standard treatment for the neurovascular sequels of both frostbite and immersion foot.[5]

The unique simultaneous inhibition of pain, shock, exudation, infection, necrosis and intoxication recommends refrigeration as an ideal treatment for burns,[29] which can also be combined with other treatments as desired. Plunging into cold water or applying ice not only gives the quickest emergency relief of pain and inflammation but also reacts most favorably on the later course. The notable case of Kross [30] illustrates two features: First, an existing infection and intoxication can be controlled by radical refrigeration in the same rapid manner as in gangrene, far superior to any possibilities of drugs. Without cleansing or débridement, the burned area is covered with a single layer of petrolatum gauze and then with ice, ice bags or apparatus. Second, the temperature after the first few days of crisis is gradually raised as high as possible without bringing return of symptoms, which in Kross's case signified skin temperatures around 60 F. for the greater part of eleven weeks. Duplication of these results requires mastery of the technic, which is rather difficult with ice but simple with the thermostatically regulated apparatus. The method is then labor saving by eliminating careful asepsis, and it is believed to offer the best control of shock and postshock intoxication and infection, the best comfort and nutrition without opiates and maximum ultimate saving of tissue.

The effective relief of sprains by superficial chilling with ethyl chloride [31] can presumably be equaled by ordinary refrigeration, with the advantage of deeper penetration if desired. Anesthesia by refrigeration without a tourniquet, preferred by some surgeons [32] for gangrene amputations, can serve for plastic and other superficial operations in nonsclerotic cases. Thus Mock [33] uses it for taking skin grafts, and Webster [34] preserves the grafts for days or weeks with cold. If there is objection to prolonged tourniquet application for stopping hemorrhage or for operative purposes, releasing the tourniquet at intervals during refrigeration still permits of perfect anesthesia, as observed by Gratz in orthopedic operations.[35] Evidence in favor of ice application as part of the routine treatment of snake bite and of all envenomed bites and stings [27] is the protracted absorption of penicillin from chilled areas [36] and the protection of rabbits from lethal quantities of mustard gas.[37] Further important uses of refrigeration await only opportunities for research, which has not been encouraged by authorities in this country.

It is obvious that the uses described have wide applications in military surgery,[38] and lives and limbs could have been saved if instructions and equipment had been provided earlier. The arbitrary dictum that refrigeration is not feasible near the fighting fronts has been answered by the actual use even with improvised apparatus. The necessity is greatest in the tropics, because of the harmful influence of heat on shock and wounds, and forthcoming publications are expected to demonstrate the benefits derived from the method in the recent Pacific campaigns. This paper is written largely with a view to wider military information and adoption.

CONCLUSIONS

Experimentation during the past six years has revolutionized the treatment of shock by substituting temperature reduction for the previous practice of warming, and replacing the former colloid or plasma concept with fluid therapy chiefly in the form of large volumes of salt solution.

Many forms of trauma can be benefited by the unique power of cold to control simultaneously pain.

ABSTRACT OF DISCUSSION

Dr. Temple Fay, Philadelphia: Drs. Crossman and Allen have done splendid work in the development of the shock prevention method of amputation surgery by means of refrigeration. This is but one aspect of the new field that awaits exploration. When one realizes that a human being can now be maintained for days at a body temperature 20 degrees F. below the normal level, the magnitude of this new field and its possibilities becomes apparent. A new physiology of tissue response awaits adequate investigation. Contrary to expectations, generalized refrigeration was not complicated by pneumonia in our series, in which low body temperatures were maintained for twenty-four hours or longer. Pneumonia and cardiac failure are two dangers to be properly evaluated. I have been impressed, however, with 2 instances in which bronchopneumonia appeared promptly when patients were subjected to a short period of inadequate refrigeration lasting two to four hours without reduction of general body temperature below 97 F. Only the devitalizing effects of ordinary overexposure is produced by such partial procedures. General refrigeration of body temperature should be done quickly and efficiently, reducing general temperature until 94 to 92 F. is reached, after which the patient can, if necessary, be maintained for five to seven days without further serious difficulty and little danger. The blood pressure, pulse and respiration must be observed and a close watch on temperature is required, as patients may slide down to lower levels quickly and without warning; 75 F. rectal is the lowest temperature I have noted in the human being compatible with recovery to normal temperature levels again. As body temperature is reduced to subnormal levels, more oxygen is held in solution in the blood, body tissue fluids and the cells themselves. Cellular metabolism is reduced by cold, and oxygen need is thus further curtailed. Satisfactory clinical improvement usually follows. A portion of the mechanism of shock is due to anoxia. Increased permeability of the capillaries to fluid may be due to lack of oxygen. Fluid lost to circulation gives rise to rapid pulse, low pulse pressure and symptoms of so-called shock that require prompt restoration of blood volume. The vasospastic drugs (posterior pituitary, epinephrine, ephedrine, ergot) are more effectual when the oxygen content of the blood is adequate and the temperature of the body is not permitted to become elevated. I have found that free administration of oxygen or an oxygen tent, if possible, is most desirable during the early period of treatment. Reduction of the entire body temperature by methods of refrigeration favors vasoconstriction, has sedational value and lowers respiratory and cardiac rates.

Dr. Harry E. Mock, Chicago: In approximately fifty major amputations under refrigeration that I performed or were done by others at my instigation, not a single case of shock has been recorded. Recently, both lower legs were amputated just below the knees of a man aged 22 because of congenital deformities. The patient continued to talk and even laugh as first one leg and then the other was removed under refrigeration anesthesia. Blood pressure readings varied 5 points throughout the operations. Neither blood transfusions nor stimulants were used postoperatively. Under any other anesthesia the fear of shock would have ruled out the removal of the two legs at one time. I welcome this opportunity to express my deepest appreciation to Fred Allen and his co-workers for teaching me to use refrigeration.

Dr. Lyman Weeks Crossman, New York: Dr. Fay has unfortunately not received the necessary aid for developing his pioneer discovery of "artificial hibernation" of mammals and man. In its practical application to this large subject of shock, the optimal rectal temperatures may possibly differ in man and animals and should be further established clinically by experts such as Fay. Until then, moderate temperature reductions appear most conservative for clinicians in general, but the essential point is that they must be brought about by Fay's method, which reduces metabolism with avoidance of discomfort and shivering, which cause increased metabolism and exhaustion. In local refrigeration we had the inestimable advantage of rapid confirmations and developments by numerous writers, and the most dramatic benefits in otherwise hopeless cases were shown in Mock's reports. In contrast to the rapid adoption by independent surgeons was the slowness of recognition of both refrigeration and saline therapy by the "organized" research authorities, to which rather than to the armed services themselves the delayed military use of these methods must be attributed. Great numbers of lives and limbs were unquestionably sacrificed by the official adherence to warming methods and pure plasma infusions, in defiance of contrary proofs published from 1937 to 1939; and the partial reforms introduced very late in the war were due strictly to the initiative of individual medical officers. These clear facts are pertinent to the current propagandistic claims that centralized control of medical research and practice will hasten the making and adoption of discoveries.

Dr. Frederick M. Allen, New York: Dr. Crossman will express the appreciation of both of us for the aid and kindness received from Dr. Fay and Dr. Mock. I wish to add only a brief reference to two developments which have come into prominence since this paper was written. While reports continue to be published showing the treatment of wounded soldiers with plasma, scientific evidence accumulates against plasma except as an inferior blood substitute and in favor of whole blood for hemorrhage and whole blood or preferably defibrinated blood (or saline suspension of red cells) for corpuscle deficits in shock. Saline therapy is advanced by various innovations, such as the replacement of isotonic solution of sodium chloride or other isotonic solutions with hypotonic solutions (e. g. 0.48 per cent sodium chloride or 0.38 per cent sodium chloride with 0.11 per cent sodium bicarbonate), for more normal bodily hydration without excessive salt retention. The curative values in shock, with its specific tissue demand for sodium, seem to be not yet finally established in comparison with various more concentrated mixtures (Moyer, C. A., and others: *Ann. Surg.* **120**:367 [Sept.] 1944. Coller, F. A., and others, *ibid.* **122**:663 [Oct.] 1945. Abbott, W. E., and others, *ibid.*, p. 678). Because of the probability that the liver plays a vital role in shock and the character of its blood supply makes it specially vulnerable to circulatory failure and anoxia, it may be hoped that the demonstrated benefits of arterial blood from a normal dog cross transfused into the splenic vein of a shocked dog may represent one of the most brilliant contributions to the theoretical understanding of shock (Fine, Jacob; Frank, H. A., and Seligman, A. M., *ibid.*, p. 652).

Pathology of the Spinal Cord as a Result of Trauma.—Injuries of the spinal cord present a slightly different pathologic picture than those of the brain. As is well known, the brain is enclosed in a rigid and practically unyielding skull, whereas the spinal cord, owing to a greater amount of free space between itself and the vertebral column, is usually allowed more mobility than the brain. The injuries of the spinal cord may result from fractures and dislocations, direct or indirect blows to the vertebral column such as falls, stabs, gunshot wounds, bomb and shell explosions, violent muscular strains and sudden changes in atmospheric pressure as in caisson disease. The pathologic changes in the cord depend on the type, extent and mechanism of the injury to the vertebral column, the spinal cord, its membranes and roots. The essential pathologic picture may be that of concussion, contusion or compression, each alone or in combination. In either type of injury, more so, however, in contusions, there may also occur lacerations, hematorachis and hematomy myelia.—Davison, Charles: Pathology of the Spinal Cord as a Result of Trauma, in Trauma of the Central Nervous System, Baltimore, Williams & Wilkins Company, 1945.

THE TREATMENT OF CIRRHOSIS OF THE LIVER WITH CHOLINE AND CYSTINE

A. J. BEAMS, M.D.
Cleveland

The treatment of cirrhosis of the liver was largely symptomatic until the past few years, when experimental studies on the etiology of cirrhosis offered the first intelligent approach to the treatment of this disease. The latest developments in the experimental studies indicate that nutritional factors are important in causing hepatic injury and that there may be prevention of this pathologic process by the proper change in the composition of the experimental diet.

In the experimental studies[1] by the various groups of investigators there is complete agreement that an inadequate amount of casein in the diet is the determining factor which causes hepatic injury consisting of fatty infiltration and degeneration, necrosis and cirrhosis. This effect of casein is explained on the basis of a lipotropic action.[2] It is generally believed[2] that this is in direct proportion to its content of methionine, which has been found to prevent experimental dietary hepatic injury when given in adequate amounts.

In addition to methionine there are other substances, choline and cystine, which are concerned in the problem of experimental hepatic injury. There is good evidence[3] that cystine administered in sufficient amounts may aggravate or cause hepatic injury, whereas choline[1] protects the liver from injury, especially from fibrosis, but has no effect on necrosis. There is some difference of opinion as to the mechanism of this action. György and Goldblatt[4] found that choline was more effective when administered with cystine, and they pointed out that in the experimental studies in which choline alone prevents hepatic injury the diets contain a certain amount of cystine.

In view of the effectual prevention of experimental hepatic injury by the combined administration of choline and cystine, the present clinical study was undertaken for the purpose of evaluating the importance of choline and cystine in the treatment of cirrhosis of the liver.

In this study only patients with cirrhosis of the liver who had ascites were selected. A group of 20 patients received from 1.5 to 3 Gm. of choline and the same amount of cystine daily divided into three doses for periods of one to five months. They were given a high protein and low fat diet which consisted of approximately 110 Gm. of protein (derived from meat, vegetables and dairy products), 50 to 70 Gm. of fat and 250 Gm. of carbohydrates supplemented with 30 to 45 Gm. of brewers' yeast daily.

Because of the manner in which these patients responded to the treatment they have been divided into two groups, one consisting of 12 patients in whom the livers were not enlarged and a second group of 8 patients who had large livers. The clinical determination of the size of the liver is subject to a certain amount of error. However, in this study, in which only the patients with large palpable livers were classified as having large livers and all of the others were considered to have livers which were not enlarged, the error is negligible.

A control group of 15 patients with large liver and ascites who had received the same diet and medication except for the choline and cystine were included in this study. The reason for selecting patients with large livers for comparison was the fact that only the patients with large livers in the treated group showed any evidence of improvement from treatment with choline and cystine.

The three groups of patients are much alike in every respect, as shown in table 1. They are in the same age group. The duration of the disease before treatment was much the same. The incidence of alcoholism was high in all of the groups, ranging from 83 to 87 per cent. Arsenic appeared to be the etiologic factor in 1 patient of the treated group who had taken solution of potassium arsenite intermittently for a long time. Jaundice was present in half of the treated groups and in 6 of the 15 in the control group. The patients of all three groups had advanced liver failure, evidenced by clinical signs and by the low serum albumin concentration.

As already mentioned, there was observed early in the course of the study a striking difference among the patients in the manner in which they responded to the choline and cystine. It was discovered that patients with large livers showed signs of improvement, while patients who had livers which were not enlarged exhibited no evidence that the course of the disease had been changed. The first 2 patients who were treated happened to have livers which were not enlarged. They received 1.5 Gm. of choline and 1.5 Gm. of cystine daily. One patient, who had the medication for fifty days, died on the fifty-ninth hospital day. An autopsy revealed a cirrhotic liver which weighed 1,060 Gm. The second patient was treated for sixty days and died on the sixty-eighth hospital day. It was then decided to increase the dose to 2 Gm. This dose was given to 14 patients, 8 of whom had large livers. Seven of the 8 showed evidence of clinical improvement. One died on the thirty-eighth hospital day after receiving choline and cystine for twenty-six days. An autopsy showed that the patient had cirrhosis of the liver and acute nephrosis. None of the 6 patients with livers which were not enlarged lived more than seven months after their first admission to the hospital. One patient died

at the end of three weeks of a ruptured esophageal varix, and 5 died of liver insufficiency. Four died within a period of four months, and 1 lived seven months. An additional group of 4 patients with livers which were not palpable was given a trial of treatment with a larger dose, 3 Gm. daily. One patient received this amount for five months and another for four months, without any apparent effect. One of these patients lived for one and one-half years, and the others died within a period of six months. Four necropsies were done in this group of patients. The livers weighed from 900 to 1,650 Gm. and the microscopic examinations were characteristic of Laënnec's cirrhosis except in 1 case, in which the anatomic diagnosis was postnecrotic cirrhosis.

In the group of patients who showed signs of clinical improvement, the first indication of response to the choline and cystine was a diuresis which began about two weeks after the medication was started. At first the diuretic effect was very slight, but it gradually increased until at the end of a month a negative water balance existed. At the end of two months ascites was not demonstrable and the livers were much smaller. The serum albumin showed a definite rise in most of these patients after a month of treatment from an average of 2.47 Gm. per hundred cubic centimeters to 3.08 Gm. per hundred cubic centimeters. At the end of three months the serum albumin ranged from 3.4 Gm. per hundred cubic centimeters to 4 Gm. per hundred cubic centimeters in all of the patients except 1, in whom the level never exceeded 2.86 Gm. per hundred cubic centimeters during a five month period of treatment. However, his ascites disappeared and the liver became smaller. The cephalin-cholesterol flocculation test became negative in only 2 patients, 1 at the end of a month and another after a period of a year.

Although none of the 7 patients showed any clinical signs of a return of liver failure, 1 of them died of a ruptured esophageal varix at the end of one and one-half years. A second patient died of bronchopneumonia after a similar lapse of time. The remaining 5 patients were enjoying good health at the time this report was completed.

The following 2 reports will serve to show how the clinical course of cirrhosis of the liver was altered by choline and cystine in the patients with large livers:

R. C., a white man aged 44, a bartender, entered the hospital because of swelling of his abdomen and feet for a period of two months. Six months prior to his admission he had experienced some nausea and indigestion at times. Two weeks before admission he had lost his appetite and had lost weight. He had drunk 1 to 2 pints of whisky a day for a period of several years. The principal physical findings were slight icterus, ascites, large liver and spleen, edema of the legs and feet, red blood cells 4.9 million, hemoglobin 90 per cent, white blood cells 12,000, cephalin-cholesterol flocculation test 3 plus, icterus index 20, serum albumin 2.4 Gm. per hundred cubic centimeters and globulin 3.2 Gm. per hundred cubic centimeters.

For three months the patient was given a high protein and low fat diet. The diet consisted of 110 to 120 Gm. of protein, 50 to 70 Gm. of fat and 250 Gm. of carbohydrates supplemented with 45 Gm. of brewers' yeast daily. How much he ate of the prescribed diet is not known, since no weigh back was done. It was estimated that he consumed less than half. During this time he had four abdominal taps and received mercurial diuretics. He showed no clinical evidence of improvement at the end of three months, following which he was given 2 Gm. of choline and 2 Gm. of cystine daily. Shortly after the choline and cystine were started there was a definite improvement in appetite. At the end of two weeks there was an increase in the amount of urine, and it gradually increased until he had a negative water balance at the end of three weeks. One month after medication was started the serum albumin was 2.8 Gm. per hundred cubic centimeters and globulin 3.5 Gm. per hundred cubic centimeters; at the end of three months the serum albumin was 3.9 Gm. per hundred cubic centimeters and globulin 3 Gm. per hundred cubic centimeters, at which time the liver was palpable just below the costal margin and there was no evidence of ascites. His serum albumin was 3.8 Gm. per hundred cubic centimeters and globulin 2.6 Gm. per hundred cubic centimeters at the end of a year. He has continued to be in good health after a period of two years.

This case represents an instance in which choline and cystine appeared to supply the factors necessary to reverse the process in the liver. They could not be supplied by diet alone because the patient was not able to tolerate large amounts of food. In instances of this kind the choline and cystine are comparable to vitamin concentrates, which are often necessary in addition to diet in the treatment of certain deficiency diseases.

Table 1.—*A Comparison of the Clinical Data of the Treated Groups with the Control Group*

	Patients Treated with Choline and Cystine		
	Livers Not Enlarged	Livers Enlarged	Control Group
Number of patients	12	8	15
Average age	49	48	50
Sex: Male	10	8	12
Female	2	0	3
Duration of disease before treatment.	2 months to 5 years	6 weeks to to 2 years	4 weeks to 2 years
Alcoholism	10	7	13
Jaundice	6	4	6
Average serum albumin	2.56 grams per 100 cc.	2.47 grams per 100 cc.	2.74 grams per 100 cc.
Average serum globulin	3.9 grams per 100 cc.	3.47 grams per 100 cc.	4.01 grams per 100 cc.
Cephalin-cholesterol flocculation test			
Positive	10	8	
Negative	2	0	

F. K., a man aged 51, entered the hospital because of abdominal swelling of three months' duration. He had been a heavy drinker of alcoholic beverages all his life. For about a year he experienced some nausea and poor appetite and had lost considerable weight. Three months before admission he noticed some swelling of his abdomen and edema of his feet. The swelling gradually increased until he entered the hospital. The chief findings were evidence of weight loss, slight icterus, edema of the legs and lower part of the back, ascites, large liver, red blood cells 3.82 million, hemoglobin 70 per cent, white blood cells 6,350, serum albumin 1.9 Gm. per hundred cubic centimeters, globulin 3.8 Gm. per hundred cubic centimeters and cephalin-cholesterol flocculation test 4 plus.

He was given a high protein, low fat diet and 45 Gm. of brewers' yeast daily. After three and one-half months of this regimen no change in his clinical condition was seen. It was necessary to do abdominal taps every week or ten days, and serum albumin remained at the same level. Choline and cystine 2 Gm. daily were added to this treatment. For the first month but little change was noticed. At the end of one month the serum albumin was 2.1 Gm. per hundred cubic centimeters and globulin 4 Gm. per hundred cubic centimeters. In the next two weeks the patient began to have diuresis, and at the end of two months no ascites was demonstrable. His serum albumin at this time was 3.5 Gm. per hundred cubic centimeters and globulin 4.9 Gm. per hundred cubic centimeters. He appeared to be in good health for a period of one and one-half years, when he suddenly died of hemorrhage from a ruptured esophageal varix.

This case serves to illustrate that fibrosis cannot be altered by treatment. This patient, after making a good recovery from liver decompensation, died of hemorrhage from a ruptured esophageal varix the result of portal hypertension probably due to the fibrotic changes still present in the liver.

In order to estimate the effectiveness of the treatment with choline and cystine, a comparison was made with the control group of 15 patients previously mentioned. From the standpoint of survival, the difference between the patients with large livers treated with choline and cystine and the control group is quite striking. One patient of the treated group was dead at the end of one year, compared to 6 at the end of six months and 9 at the end of a year in the control group. Only 6 patients in the treated group have been observed as long as two years, at the end of which time 3 had died, compared to 10 in the control group (table 2). The results of the treatment are disappointing when the patients with livers not enlarged are included. Fifty-five per cent were living at the end of six months. At the end of one year 40 per cent survived, and at the end of two years 16.6 per cent.

TABLE 2.—*A Comparison of the Survival of the Choline-Cystine Treated Patients with the Control Group of Patients with Cirrhosis Treated with a High Protein, Low Fat Diet*

	Number of Patients	Survival Period		
		6 Months	1 Year	2 Years
Patients with livers not enlarged	12	4	1	0
Patients with large livers *.......	8	7	7	3
Control group....................	15	9	6	5

* Two patients of this group have been followed only one year.

In the evaluation of any therapy for cirrhosis one must realize that spontaneous remissions sometimes occur, and there are stages of the disease at which the process is irreversible. There are no clinical signs or liver function tests which are of any help in detecting clinically when this stage has been reached. When these facts are taken into consideration it is quite apparent that it will be necessary to study large groups of patients in order to establish any definite conclusions as to the efficacy of a treatment.

In this investigation, in which only a small number of patients were studied, the possible merits of the combined administration of choline and cystine therapy for cirrhosis cannot be decided. However, the results which were obtained are sufficient to warrant further investigation of this form of treatment. In the group of patients with large livers the results are very encouraging when compared to the control group. Additional evidence for the efficacy of the treatment is that some of the patients improved with choline and cystine after they failed to respond to a high protein, low fat diet supplemented with yeast.

The difference noticed in the response to choline and cystine between the patients with large livers and those with livers not enlarged appears to be of considerable importance. It suggests that the size of the liver may give some indication whether the process can be reversed by treatment. It is generally agreed that, as the fibrosis increases, the liver becomes smaller and the possibility of obtaining a reversal of the process becomes less. On the other hand, the large cirrhotic liver in most instances contains more fat and less fibrosis. Fleming and Snell[5] found in their study that favorable results occurred in patients with large livers, and they expressed the opinion that the "cures" probably are to be expected among the patients who possess various degrees of fatty metamorphosis and degeneration without extensive periportal fibrosis. There seems to be general agreement that treatment is more effectual when there are fatty changes in the liver. However, other changes such as cloudy swelling and necrosis, which are characteristic microscopic findings in cirrhotic livers, may be altered by treatment.

Since the combined administration of choline and cystine was effective only in the patients with large livers where fatty changes were suspected, a lipotropic action of choline and cystine is the logical explanation for the results which were obtained. These results are what might be expected in view of the experimental studies[1] in which choline, the combination of choline and cystine, or methionine has been found to prevent the deposition of fat in the liver.

The only reference which can be found in medical literature as to the clinical use of choline and cystine in the treatment of human cirrhosis is that of Russakoff and Blumberg,[6] who report a personal communication from Gordon. He[7] observed striking improvement in 5 cases of alcoholic cirrhosis treated with a combination of choline and cystine. There are several clinical reports[8] in which choline in conjunction with a high protein, low fat diet and vitamin supplements appeared to exert a favorable influence in the treatment of cirrhosis.

The favorable results in the treatment of cirrhosis of the liver reported by Patek and Post[9] and by Fleming and Snell[5] with high protein diets and vitamin supplements must be attributed to certain factors in the proteins which arrest or reverse the process in the liver. On the basis of the present experimental studies choline, a combination of choline and cystine, and methionine are the only substances which are known to exert this action. There is a close analogy between cirrhosis of the liver and certain vitamin deficiency diseases in which diet alone may correct the condition when it can provide a sufficient amount of the deficient factors. However, when diet does not do this vitamin concentrates must be supplemented.

CONCLUSION

It is important to emphasize the limitations of the treatment of cirrhosis. Up to the present time there has been no treatment which has been found that alters fibrosis of the liver. Recovery of liver function therefore must depend on the arrest or reversibility of the other pathologic changes which are found in cirrhosis.

SUMMARY

1. Twenty patients with cirrhosis of the liver who had ascites were treated with a high protein, low fat diet supplemented by yeast and a combination of choline and cystine.

2. Twelve of the 20 patients with livers which were not enlarged showed no response to the therapy, whereas 7 of the 8 patients with large livers made a good recovery from liver decompensation.

3. A comparison of the treated group of patients with large livers with a similar group of 15 patients who were treated with only a high protein, low fat diet supplemented with yeast indicated that the combination of choline and cystine had a favorable influence in the treatment of cirrhosis.

4. The striking difference in the response of patients with large livers compared to patients with livers not enlarged suggests that the combination of choline and cystine is effective where fatty changes in the livers are suspected.

ABSTRACT OF DISCUSSION

Dr. James H. Eddy Jr., Shreveport, La.: The importance of certain nutritional factors in the treatment of hepatitis appears to rest on good laboratory and clinical evidence. The sulfur containing amino acid methionine or cystine plus choline is apparently the essential factor. That either methionine or cystine plus choline has any advantage over the other is doubtful unless it is the simplicity of using one drug in place of two. My experience has been entirely with methionine, but results obtained with methionine could be expected to occur with cystine plus choline. My work has been neither as extensive nor as well controlled as Dr. Beams's has been, but the results seem to be roughly parallel. All of our late cases have been fatal in spite of treatment, although a definite if temporary improvement occurred in 1 case, in which a notable diuresis followed the administration of methionine; but death in coma took place within a few weeks. Of the 2 earlier cases only 1 is proved by microscopic study, but both are definite early cases of cirrhosis. Both of these patients had large livers and both have shown a good improvement, so that they have been able to return to their regular jobs, have become clear of jaundice and have good appetites. I believe that much more clinical work will be required to establish the place of these nutritional factors in the treatment of cirrhosis and that these patients must be followed for several years to determine how permanent this improvement will be. One thing seems certain, and that is that these patients must be treated early, as no medical management may be expected to relieve portal obstruction.

Dr. Nolan Kaltreider, Rochester, N. Y.: Dr. Beams points out that it is quite difficult to evaluate the effectiveness of any one particular therapeutic agent in human beings with cirrhosis of the liver. The course of the disease is very variable and there are many factors that are beyond the control of the investigator. Even though the reported group of cases of cirrhosis of the liver treated with a mixture of choline and cystine is quite small, such clinical observations do serve well as pilot experiments. Pooling the results of such series from various clinics will make it possible in the near future to have a large enough series to apply statistical methods in an effort to evaluate the results. This study suggests that choline-cystine supplements are much more effective in cases in which the livers are enlarged by fatty infiltration or degeneration and by necrosis than in the stage in which the livers are small, presumably contracted by fibrous tissue. If this result is substantiated, it should be an important point in the prognosis of the disease. It would be of interest to know the dietary intake of the control group, for from the 2 cases reported in detail in the paper it appears that an adequate caloric intake was not possible prior to the administration of the supplements. Patek obtained very encouraging results in a group of patients with cirrhosis who were placed on a high protein, carbohydrate and low fat diet supplemented by large quantities of yeast. But he points out that in order to obtain such improvement it is necessary for the patient to receive a high caloric intake daily. In a small series of cases treated with a high protein, carbohydrate, low fat diet and with supplements of choline-cystine mixture of methionine, improvement (disappearance of symptoms, return of the electrophoretic pattern to normal and normal liver function) was observed provided the patients took an adequate caloric intake and reduced their alcoholic consumption. Whether or not these patients would have improved with an adequate diet without the supplements I am not prepared to say. The disease in one of the patients with large liver has continued to progress despite fairly large doses of choline-cystine mixture and methionine over a period of one year. This patient did not take the diet prescribed and he continued to consume large amounts of alcohol. On the other hand, another patient with almost identical findings is now clinically well with a reversion of the albumin globulin ratio to normal, a normal electrophoretic pattern and a normal liver function. The second patient has taken a high caloric diet and supplements and has abstained from the use of alcohol. These experiences with supplements of yeast powder, choline-cystine mixture and/or methionine, in addition to a high caloric diet and abstinence from alcohol suggest a very favorable prognosis for persons suffering from cirrhosis of the liver, especially those in the early stages of the disease before the pathologic process becomes irreversible.

Dr. Charles L. Hoagland, New York: There are differences between the syndrome of chronic hepatic insufficiency accompanied by clinical signs of enlargement of the liver and the cirrhotic syndrome in which the liver is not palpable and therefore probably decreased in size. The prognosis is far better in the former type of cirrhosis, and it is in the group of patients who present signs of enlargement of the liver that by far the largest number of spontaneous remissions occur. It is in this group also that the best therapeutic results have been achieved with an adequate diet, rest, transfusions of blood, plasma and homologous albumin, and the administration of crude liver extract and vitamins. Incipient cirrhosis is characterized by fatty infiltration and enlargement of the liver. As the disease advances there is continued proliferation of connective tissue throughout the portal spaces of the liver, with eventual fusion and deformity of the hepatic lobules. In its final stages the disease process is associated with shrinkage in the size of the liver and a decrease in its total mass. Logically, therefore, the sooner rational treatment is begun in cirrhosis of the liver the greater are the chances that the course of the disease may be favorably influenced. If choline and cystine are truly helpful in the treatment of cirrhosis of the liver, but only in those cases which present signs of hepatic enlargement, success in the use of this type of therapy may well be due in a large measure to early initiation of treatment, including the prompt institution of adequate alimentation and good clinical care. If we are right in the supposition that chronic hepatic insufficiency is a multiple deficiency syndrome, it would be well to stress the use of adjuvant therapy of the most diverse type rather than to rely exclusively on one or more promising agents. Any measure which may be expected to relieve one or more of the metabolic defects arising in this complex syndrome should be included in the therapy of chronic hepatic insufficiency. Measures such as an adequate caloric intake, transfusion of blood, plasma and homologous serum albumin, and the administration of choline, the sulfur-amino acids, crude liver extract and the vitamins may be expected to contribute to some degree in raising the total metabolic efficiency of the liver and to play an important role in helping to check the processes at work in early cirrhosis of the liver, which, if uninfluenced, lead ultimately to a state of irreversible hepatic insufficiency and death.

Dr. Paul György, Philadelphia: The use of choline plus cystine, or of methionine, in the treatment of cirrhosis of the liver in man is based on results obtained in experimental animals in which hepatic injury (necrosis and cirrhosis) was produced by dietary means or after exposure to hepatotoxins. Methionine, or cystine plus choline, has a beneficial effect on both necrosis and cirrhosis, choline on cirrhosis, cystine in physiologic doses mainly on necrosis. These animal experiments were with few exceptions of prophylactic and not of therapeutic nature. It can be rightly questioned whether cirrhosis, with its massive fibrotic changes and destruction of normal architecture, will respond also therapeutically to dietary factors which determine its prevention. On the other hand, it should be borne in mind that cirrhosis is more than fibrosis and is usually associated with definite impairment of liver function. Failure to inactivate estrone is one of the manifestations of experimental dietary hepatic injury. It can be studied on living castrated female rats with pellets of estrone implanted in their spleen. Estrus appearing in such animals when kept for varying lengths of time on a cirrhosis producing ration can be suppressed by adding methionine or methionine-containing protein to the diet. This therapeutic effect of methionine and protein can also be demonstrated histologically by comparing sections of the liver taken by biopsy from animals that have been kept for a period of about one hundred and fifty days on a cirrhosis producing basal diet, with sections taken at autopsy of the same animals killed one hundred and fifty days after treatment. In addition to diet, endocrine factors appear to play an important role in experimental hepatic injury. It has been recently shown that estrone exerts a definite, although limited, protective effect on the liver on female rats fed a cirrhosis producing diet. Testosterone or methyltestosterone were without similar beneficial influence. In male rats exposed to carbon tetrachloride the survival time was shorter and parenchymatous changes, especially in the kidneys as part of the hepatorenal syndrome, were more evident than in identically treated female controls. Methionine has shown definite protective effect in both groups, relatively more pronounced in males. The protective effect of thiouracil in experimental hepatic injury might conceivably be regulated through the thyroid gland. It remains to be shown whether management of human cirrhosis of the liver will improve by combination of dietary and endocrine therapy.

Dr. A. J. Beams, Cleveland: I agree with Dr. Eddy that choline and cystine have no advantage over methionine in the treatment of cirrhosis. In the past year I have employed methionine in the treatment of a group of patients with cirrhosis and hepatitis, and the results are similar to those obtained with choline and cystine. Dr. Kaltreider's inquiry as to the dietary intake of the patients in the control group cannot be answered, since the food they failed to eat was not estimated. They were given a high protein (approximately 110 Gm.) low fat and high carbohydrate diet (2,000 to 2,500 calories), which was the same diet employed in the group treated with choline and cystine. Since many of the patients who have cirrhosis with ascites are too sick to take an adequate diet, the report of good results in the treatment of cirrhosis with diet alone is surprising. Since Dr. Hoagland agrees that the best therapeutic results are obtained in the group of patients with large livers and fatty infiltration, it is difficult to understand why he doubts that a lipotropic substance such as choline plus cystine would not be helpful in the treatment of cirrhosis. I agree that there are evidences for multiple metabolic deficiencies in chronic liver insufficiency, and every measure which may relieve the metabolic defects should be employed. However, in cirrhosis, just as in many of the other deficiency diseases, there is good evidence of one factor being the essential cause of the disease, and the other metabolic defects are the result of the disturbed metabolism. This is especially true in the liver, where many metabolic processes occur. It is quite true that additional experimental and clinical evidence is necessary before it can be established that choline plus cystine or methionine is the essential nutritional factor that is required in the successful treatment of cirrhosis of the liver.

REACTION FOLLOWING BRONCHOGRAPHY WITH IODIZED OIL

CAPTAIN GEORGE S. MAHON
Medical Corps, Army of the United States

Severe or fatal reactions are relatively rare following instillation of iodized oil into the tracheobronchial tree. Information is furnished[1] that the Army Institute of Pathology has on file the protocol of only 1 case that might possibly be a fatal lipiodol reaction after intrabronchial instillation, and that case is the one reported herein. It is estimated[2] that about 300 bronchograms, representing some 200 individual patients, are performed yearly in the Section on Roentgenology of the Mayo Clinic. Nevertheless, according to Good, "there has never been a fatal accident following bronchography in the memory of any one, including myself, who has worked in this field at the clinic." Patients at the Mayo Clinic are not tested for iodine sensitivity prior to lipiodol bronchography unless they give a history of sensitivity to iodine. Among those patients who are sensitive to iodine, about six mild reactions occur each year, but all have been controlled without fatality. White and Bayliss[3] could find only 8 cases of severe reactions, 3 of them fatal, reported in the literature to time of writing (1943), and to these 8 cases they added 1 nonfatal case of their own.

They state that "no similar case has previously occurred in Sydney (Australia) following lipiodol bronchography. One of our radiological colleagues has made 2,000 lipiodol examinations of the bronchial tree with no untoward results." Scadding[4] had 2 cases of severe reaction to lipiodol (included in summary of literature by White and Bayliss), 1 of them fatal, and he states that "over 2,900 lipiodol examinations have been performed at this hospital without a previous serious accident from iodine sensitivity." Criep and Hampsey[5] circulated a questionnaire on the use of intratracheal iodized oil in bronchial asthma. Sixty-four of the physicians who replied had used iodized oil in examining 1,205 asthmatic patients and did not report a fatality. Ten other cases of severe reaction following lipiodol instillation can be found in the literature,[6] but no figures are given on the total number of uneventful lipiodol instillations represented by the ten severe reactions, five of which were fatal, five nonfatal. One of the patients who died[7] was a 13 year old girl, known to be asthmatic, who became cyanotic with weak pulse and died twenty hours after instillation of lipiodol. The autopsy findings were those considered typical of bronchial asthma. Another patient[8] died a few minutes after bronchoscopy with instillation of lipiodol, but since no details are given it is not possible to rule out some type of death other than iodized oil reaction, e. g. fatal reaction to local anesthetic. The other three

fatalities[9] are reported so briefly that one cannot form an adequate idea of the cause of death; and it cannot be certified that these deaths were reactions to iodized oil per se. The reactions in the 5 nonfatal cases[10] were diagnosed acute massive collapse of the lungs, but of course the actual pathologic condition can never be known. Amberson and Riggins[11] believe that the 4 cases of Jacobaeus, Selander and Westermark[10] were cases of pulmonary edema rather than atelectasis, but careful reading of the original report makes it appear that the cases actually fulfilled the clinical and x-ray criteria of pulmonary collapse and should be considered such.

It is significant, with regard to the factor of iodine sensitivity, that in the case reported by White and Bayliss[3] and in the nonfatal case reported by Scadding,[4] a previous instillation of iodized oil had been given without any reaction; also that no severe or fatal reactions to lipiodol have been observed at the Mayo Clinic to date, even in patients known to be sensitive to iodine.[2] Further, the patient of White and Bayliss gave a negative reaction to iodine when tested for sensitivity after the acute reaction had subsided, and Scadding's patient with a severe but nonfatal reaction had been taking iodide by mouth previous to the lipiodol injection but had not shown any symptoms of iodine sensitivity.

The types of reaction that may occur following use of iodized oil have not been found classified in the available literature. The reactions that are seen in the Mayo Clinic groups are classified as follows:[2]

1. Swelling of the parotid and submaxillary glands, beginning shortly after instillation of the oil and subsiding within twenty-four to forty-eight hours. This is the most common reaction, is seen three to four times a year, and occurs in patients without allergic history.
2. Asthma, occurring about once a year, always in persons who show other signs of allergy.
3. Urticaria, beginning almost immediately, not occurring over once a year and "probably on an allergic basis."
4. Skin eruption, papular or pustular, occurring ten to fourteen days after the instillation of the oil, similar to a drug eruption and not seeming to have an allergic basis.

Scadding[4] notes that he had had frequent mild reactions prior to the two severe ones, and these mild reactions were usually a transient coryza with lacrimation, and possibly mild urticarial or erythematous rashes, all passing off within a few days; while less frequently more severe rashes of an acute irritant and urticarial type occurred seven to ten days after injection; and headaches occurred rarely. All the cases reported in the literature primarily as reactions to lipiodol[12] have been classified as "acute iodism" and have been characterized by dermal lesions of a type described as hemorrhagic, bullous urticaria. The other reactions reported in the literature[6] either represent pulmonary reactions or are not described adequately to determine the exact type of reaction involved, and these cases are reported incidental to other subjects, such as various studies of asthma, diagnostic or pathologic, or studies of the use of iodized oil as a therapeutic agent in asthma.

The following case is reported because it is believed to be unique as a case of fatal pulmonary reaction following instillation of iodized oil into the tracheobronchial tree, and caused by reaction to the iodized oil.

REPORT OF CASE[13]

History and Course.—A white man aged 41 was admitted to the hospital with the chief complaint of gastroenteritis. He had had abdominal pain for three days prior to admission and became nauseated on the day of admission. The past history was negative except for a note of occasional cough of apparently nonspecific nature. No history was taken about asthma specifically. Physical examination on admission was entirely normal except for a temperature of 101.8 F., pulse rate 104, respiratory rate 24 and slight tenderness in the gallbladder region. Laboratory studies on admission showed normal urinalysis, red cells 4.4 million, white cells 7,750 with 72 per cent neutrophils, 28 per cent lymphocytes and blood Kahn reaction negative. The signs and symptoms of gastroenteritis cleared within twenty-four hours, and then physical examination showed a few rales in each base and in the left upper chest posteriorly. On account of these rales, x-ray examination of the chest was ordered and the sedimentation rate of the blood was determined. The sedimentation rate was 26 mm. per hour (Cutler method). The x-ray was reported as showing some increase in lung markings throughout both lung fields, more definite in the right base, which had a honeycomb appearance which was somewhat suggestive of a bronchiectasis. The patient was referred to the eye, ear, nose and throat clinic for a lipiodol injection for visualization of the right lower bronchial tree. At 8:15 a. m. the patient was given 1½ grains (0.1 Gm.) of seconal by mouth, and at 8:45 a. m. the larynx was anesthetized with topical application of 3.5 to 4 cc. of 10 per cent solution of cocaine. A rubber tube was inserted into the trachea; the patient was taken to the x-ray room on a cart and 10 cc. of lipiodol was injected into the base of each lung. The x-ray examination was completed, the patient stated that he felt well and he was returned on a litter to his ward at about 10 a. m. He complained of some vague difficulty in breathing when he was first returned to the ward but didn't seem greatly troubled by it. He asked for some coffee and drank about a cupful without any apparent distress or difficulty. About twenty minutes later he had a severe generalized convulsion. An intravenous dose of 7½ grains (0.5 Gm.) of sodium amytal was given within one minute of the time of onset of the convulsion because the possibility of a cocaine reaction was considered. A few minutes later the patient became extremely cyanotic and stopped breathing. Artificial respiration was given for about thirty minutes, and he was pronounced dead at 11:20, about ninety minutes after cocainization of the throat and about seventy-five minutes after instillation of the lipiodol.

Autopsy.—This was performed one and one-half hours after death. The body was well developed and nourished, still warm, with slight but definite rigor of the extremities and a diffuse dependent lividity of mild degree. General external examination was not remarkable. The peritoneum and peritoneal cavity were normal. When the thoracic cage was opened, the left lung was found collapsed, filling only about one third of the chest space. The surface of the right lung was covered with dense fibrous adhesions which bound it tightly to the chest wall everywhere except over the apex and the base. When these adhesions were broken, the right lung immediately collapsed to the size of the left lung. The left lung weighed 300 Gm., the right lung 400 Gm. Both lungs, when removed, were noncrepitant, and except for the apex and base of the right lung the cut surface had the appearance of atelectatic lungs. The tracheobronchial tree was completely filled with thick, extremely tenacious mucus. This material was found plugging even the smallest bronchioles at the base of the lungs. The tracheobronchial mucosa was pink and velvety in appearance. The pulmonary vessels were patent and were free of thrombi or emboli. There was no gross evidence of tuberculosis in either lung or in the tracheobronchial lymph nodes. The right ventricle of the heart was dilated and filled with black fluid blood; the left ventricle was contracted and empty. The coronary arteries were normal and patent. The spleen, liver, gallbladder, adrenal glands, venae cavae and pelvic veins, pancreas, kidneys and genitourinary tract, scalp, skull, brain and cord were examined and found to be grossly normal. The stomach was contracted and contained only a small amount of brown, semiliquid material with a coffee-like odor. No oil was seen in the stomach. The remainder of the gastrointestinal tract was entirely normal.

[13] Army Medical Museum accession 126310.

Postmortem Laboratory Studies.—Urinalysis gave normal results throughout.

Chemical examination of the blood from the right ventricle revealed 363.6 mg. of sugar and 16.6 mg. of urea nitrogen per hundred cubic centimeters. The corresponding figures for blood from the aorta were 322.6 mg. and 12.8 mg. per hundred cubic centimeters.

3. The spinal fluid was clear and colorless, with 4 lymphocytes. The Pandy test was slightly positive. The Kolmer reaction was negative in all dilutions, sugar 69.9 mg. and chlorides 672.7 mg. per hundred cubic centimeters.

A smear of the bronchial mucus revealed a few cells, chiefly neutrophils and lymphocytes, with 1 per cent or less eosinophils. No organisms were present in gram stained or acid fast stained slides.

Microscopic Examination.—The trachea and main bronchi showed an occasional eosinophil infiltrating the mucosa and a moderate number of eosinophils together with an increased number of small round cells infiltrating the submucosa. The mucous glands showed evidence of activity, but only rarely was an eosinophil seen present immediately adjacent to the mucous gland units. The appearance of the intrapulmonary air passages showed great diversity. The bronchi and largest bronchioles had thickened, infolded mucosa, and the lumens were stenosed and filled with mucus in which were a very few lymphocytes and neutrophils but no eosinophils. The basement membrane was thickened and hyalinized. There was no cellular infiltrate in the submucosa or walls of these larger air passages. The smaller and terminal bronchioles were dilated, and their epithelial lining was thinned and flattened and often eroded. Their dilated lumens were filled with mucus in which were many eosinophils, neutrophils and neutrophilic cell débris. The bronchiolar walls and the peribronchiolar tissues were heavily infiltrated by eosinophils, neutrophils and lymphocytes. The tissue eosinophilia in these areas was quite striking and seemed to be directly related to the severity of the dilatation of the lumen and cellular content therein. The degree of atelectasis varied from completed to partial, and in some areas of sections from the upper lobes there were large excessively dilated alveoli, with thickened walls, suggestive of chronic emphysema. The pulmonary parenchyma in all sections showed varying degrees of fibrosis.

The spleen and wall of the esophagus showed a diffuse eosinophilia.

Sections from the heart, aorta, liver, pancreas, adrenals, stomach and intestine, genitourinary tract and central nervous system were normal.

The final pathologic diagnoses of significance were :

1. Obstruction, tracheobronchial, bilateral complete, due to inspissated mucus.
2. Massive pulmonary collapse due to 1.
3. Death from asphyxia due to 1 and 2.
4. Bronchiectasis and bronchiolitis mild to moderately severe, involving each lower lobe.
5. Fibrosis, pulmonary, bilateral patchy disseminated, moderately severe.

COMMENT

The sudden and unexpected death of this patient, with attendant convulsions, suggested at first the possibility of cocaine poisoning. This was ruled out by the time interval and the pathologic changes. It is agreed that the symptoms of cocaine poisoning occur within a few minutes after the use of the drug,[14] a conclusion which King [14] based on study of 43 deaths due to local anesthesia. In this case at least an hour elapsed between the time of cocainization and the terminal episode. Further, postmortem examination of 20 deaths due to cocaine or cocaine derivatives failed to reveal any remarkable pathologic features other than venous congestion,[15] while in this case the gross and microscopic pathologic changes are very striking.

It is obvious that the immediate cause of death in this case was asphyxia due to the plugging of the bronchial tree by thick viscid mucus. The asphyxial nature of this death is confirmed by the terminal hyperglycemia in the arterial circulation, a finding which has been noted as a characteristic postmortem finding in deaths due to asphyxia.[16] The atelectasis followed secondary to the obstruction of the air passages and the absorption of the alveolar air by the alveolar capillaries during the agonal struggles. The convulsions were due to cerebral anoxemia.

The real question involved in this case is why the bronchi should have so suddenly filled with mucus and thus begun the fatal chain of events.

Except for the vague complaint of dyspnea when the patient first returned to the ward from bronchography, a symptom probably indicative of the onset of the filling of the bronchial tree with mucus, he had not had any symptoms or signs of asthma while under observation. Nevertheless the autopsy finding of thick mucus filling the tracheobronchial tree suggested asthma as an etiologic factor in the case. Authorities agree that the following features are characteristic of the lungs of patients who die of asthma per se:[17]

1. Grossly: (*a*) Lungs distended and voluminous, emphysematous and doughy in consistency. (*b*) Bronchi and bronchioles filled with viscid, tenacious mucus.

2. Microscopically: (*a*) Thickening and hyalinization of the basement membrane of bronchi and bronchioles. (*b*) Thickening and infolding of mucosa in bronchi and bronchioles. (*c*) Cellular infiltrate in mucosa and submucosa, composed of eosinophils, lymphocytes and plasma cells in varying proportions. (*d*) Mucous plugs in lumens of most bronchi and bronchioles, with the same type of cells in the mucus as are present in the tissues. (*e*) Hypertrophy of the musculature. (*f*) Evidence of hyperactivity of mucus-secreting glands, with pressure atrophy of acinar cells.

Tuft [18] agrees in general with the foregoing list of pathologic changes characteristic of asthma but states that, in certain cases in which the mechanism of death is mechanical obstruction of bronchi by sticky, gelatinous exudate, "partial or complete atelectasis may be present." However, no references are given, and the remainder of the literature cited, including Rackemann's thorough and critical review article, does not mention this possibility.

[18] Vaughan: Practice of Allergy, p. 271.

It is evident that the case reported here presented the pathologic features described as characteristic for asthmatic deaths, except that atelectasis, instead of emphysema, was the outstanding gross pathologic feature. Of course, as Rackemann[19] points out, there must be a clinical history of asthma in order to classify a death as "death from asthma per se"; and in this case that history must remain only a matter of conjecture, because the possibility of asthma did not suggest itself while the patient was alive, and specific inquiry was not made. Nevertheless, in spite of a lack of history of asthma, the microscopic findings are so consistent with those of allergic asthma that there must be considered the possibility of an asthmatic substratum in the tracheobronchial tree at the time of instillation of lipiodol. Furthermore, tissue eosinophilia is known and recognized as evidence of allergic response,[20] and it is stated that when edema and eosinophilia are found in the tissues there is strong suspicion of the allergic character of the lesion. The conclusion seems justified that the bronchi and bronchioles in this case were allergically prepared to act as a shock organ in an allergen-antibody reaction and that the allergen responsible for the fatal reaction was lipiodol, probably the iodine fraction, since allergic sensitivity to iodine is well known and may cause very severe and even fatal reactions.[21]

The fatal reaction may be reconstructed as follows: The patient was allergic, sensitive to iodine and possibly to other substances also, and his bronchial-bronchiolar tree was specially sensitized as a shock organ. The instillation of lipiodol brought allergen (iodine?) into direct contact with the shock organ and by reason of its contact in relatively high concentration produced a rapid and intense asthma-like response in which the predominant feature was secretion of viscid mucus. Respiratory obstruction, asphyxia, cyanosis, convulsions and death then followed.

CONCLUSION

In this patient the tracheobronchial tree was allergically prepared to act as a shock organ. The patient had allergic sensitivity to some constituent of lipiodol, probably the iodine. The immediate contact between allergen and shock organ produced a rapid and severe asthma-like reaction in which the production of thick mucus predominated, causing bronchial obstruction, massive pulmonary collapse and death from asphyxia.

Clinical Syndromes of War Neuroses.—Of all neuroses of war, these severe anxiety states present the most interesting diagnostic and therapeutic problems. No two clinical pictures are ever the same; each case represents a unique combination of symptoms, as highly personal as the combination of character traits which make up an individual personality. It is almost an impossibility to predict in any one case what course the illness will take; new symptoms may appear with startling suddenness and as rapidly disappear. Similarly it is difficult to anticipate how much spontaneous recovery will take place. Because of the severe initial distortion in personality from friends or relatives concerning the previous behavior of the individual patient, the preexistent personality structure and stability of the individual remain an assumption, and on this assumption must be based estimates of the degree of recovery.—Grinker, Roy R., and Spiegel, John P.: War Neuroses, Philadelphia, Blakiston Company, 1945.

TOXIC MANIFESTATIONS ASSOCIATED WITH PROLONGED ERTRON INGESTION

SMITH FREEMAN, M.D., Ph.D.; PAUL S. RHOADS, M.D.,
and
LEONA B. YEAGER, M.D.
Chicago

The effects of large doses of vitamin D on animals were described in detail some years ago.[1] Since the amounts of vitamin D required to produce toxic effects were far beyond that necessary for the prevention or treatment of rickets, these results seemed, at the time of their presentation, to be largely of academic interest. However, the use of large doses of vitamin D in the treatment of arthritis has exposed a great number of people to the hazards of hypervitaminosis D. For this reason it is important to renew interest in the effects of vitamin D overdosage and to emphasize again, as others have done recently,[2] the symptoms and consequences of its toxicity.

the seriousness of the toxic effects which it produced. Others[4] have pointed out the variable response of human beings to large doses of vitamin D and the possible damage to the kidneys which may result from its use.[5] The manufacturers of one vitamin D preparation, Ertron, have consistently maintained that serious toxic effects have not resulted from the use of their preparation. However, Boots[6] observed toxic manifestations in 18 of 31 arthritic patients who received Ertron, and Freyberg[7] stated that it has real potentialities for producing undesirable effects. McChesney and Messer[8] demonstrated that it was a potent hypercalcemic factor when administered to dogs in large amounts. One of us[9] called attention in 1942 to the false sense of safety which the advertising mentioned engendered in the mind of the physician who used such preparations in the treatment of arthritis.

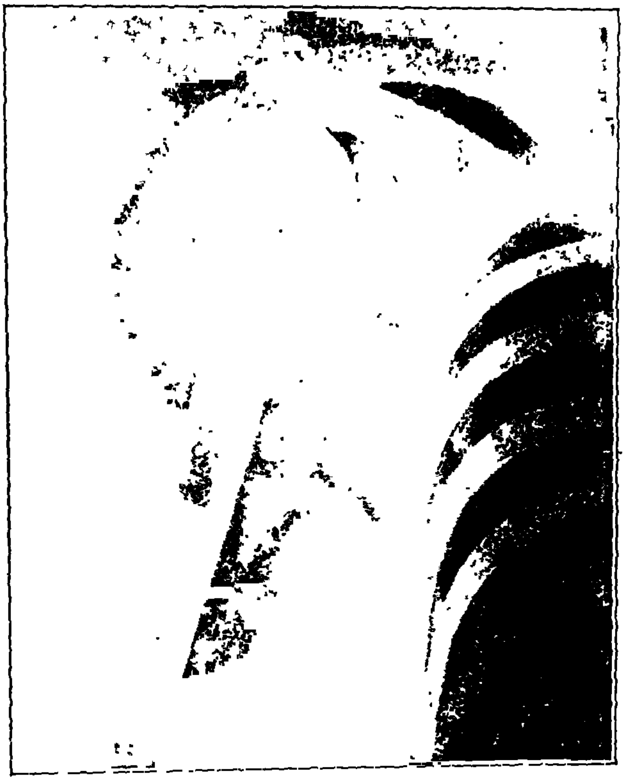

Fig. 1 (case 1).—Right shoulder in September 1944, showing metastatic calcification associated with prolonged Ertron medication.

There seems to be general agreement regarding the view that doses of vitamin D such as are used in the treatment of arthritis may be toxic. However, there is a difference of opinion as to how serious these toxic reactions may be. That such reactions may be sufficiently serious to jeopardize life and health is evidenced by the severe renal insufficiency recently reported by Danowski, Winkler and Peters[10] as occurring in 2 patients who had received 150,000 to 500,000 units of vitamin D daily. The following case reports are presented as further evidence of the fact that severe renal insufficiency and disability may result from the ingestion of doses of Ertron such as are currently used in the treatment of arthritis. The data on case 3 demonstrate that the product reduced calcium retention by a child with rheumatoid arthritis.

Case 1.—A white man aged 49 was admitted to a hospital Feb. 25, 1945 because of weight loss, weakness, anorexia, desquamation of the skin, polyuria, pruritus and bursitis.

The patient stated that he took Ertron irregularly in 1942, including one period of 300,000 units daily for three months, because of bursitis of the right shoulder. In March 1943 he had a prostatectomy and at that time he had some nitrogen retention. Ertron medication was resumed at this time (100,000 units per day) for three months. His weight in 1943 was 145 pounds (66 Kg.).

During the winter of 1943 and early spring of 1944 the patient suffered from generalized pruritus, weakness and shortness of breath. In March he took a vacation and during this time experienced some ataxia and developed an effusion of the right shoulder and hip. In May 1944 he was admitted to a diagnostic clinic because of weakness, anorexia and a loss of weight. The outstanding physical findings at this time were exfoliative dermatitis and enlarged inguinal lymph nodes. The weight was 112 pounds (51 Kg.), the blood pressure 116/72. X-ray films of the chest and stomach were normal. The laboratory findings at this time and subsequently are included in tables 1 and 2. A diagnosis of chronic glomerular nephritis with renal insufficiency and severe secondary anemia was made and the patient returned to his home, where his condition remained unchanged.

In September 1944 he entered another hospital complaining of generalized itching, weakness, fatigue, exfoliation of the skin and pain in the breasts.

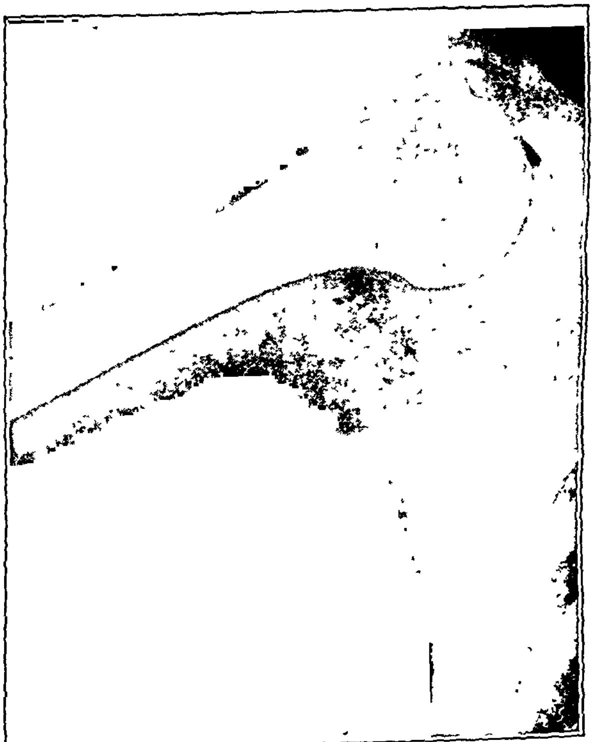

Fig. 2 (case 1).—Right shoulder in February 1945, six months after ingestion of Ertron and a high milk diet had been discontinued.

At this time his weight was 102 pounds (46 Kg.), his blood pressure 106/66. There were emaciation and exfoliation of the skin, connective tissue deposits on the conjunctivas and tender breasts, the right one being enlarged and fluctuant. The right shoulder bore a large soft tumor and showed slight limitation of motion. The ankles were somewhat edematous, the prostate slightly enlarged. X-ray examination revealed calcium deposits in the soft tissues at many points (figs. 1 and 2). It was noted that the patient largely restricted his intake to water, milk and milk dishes. He complained bitterly of the cold. The patient was diagnosed as having pityriasis rubra, deposits of calcium in the bursae and benign hypertrophy of the prostate.

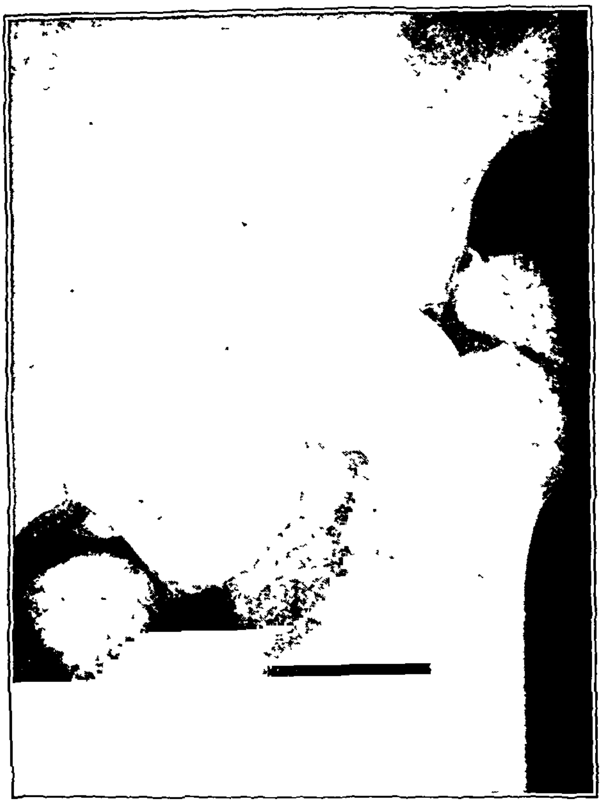

Fig. 3 (case 1).—Left side of pelvis in September 1944, showing calcification above hip joint and in prostate.

Part of the laboratory data obtained at this time are included in table 1.

During the latter part of 1943 and the first half of 1944 the patient stated that he took with some irregularity 100,000 to 300,000 units of Ertron daily.

At the time of admission to the original hospital, Feb. 25, 1945, the patient stated that he had not had any Ertron since September 1944. At this time he also discontinued drinking milk in accordance with instructions given him at the second hospital. The principal physical findings at the time of this admission to the first hospital were weight 118 pounds (53.5 Kg.), blood pressure 112/72, generalized exfoliation and pigmentation of the skin, emaciation, moderate pitting edema of the lower extremities and heavy fat deposits in the conjunctivas. X-ray examination again revealed extensive calcification about numerous joints, but these deposits were less dense than shown on the films taken in September 1944. The excretion urograms showed poor kidney function The patient had a subnormal body temperature throughout his stay in the hospital. He was diagnosed as having Ertron intoxication, exfoliative dermatitis and subdeltoid bursitis.

Since leaving the hospital the patient's urinary calcium has remained elevated. Roentgenologic examination of the right shoulder and hip taken July 23, 1945 indicates that there is still some soft tissue calcification, but the deposits are less dense and extensive than on the previous films (figs. 1, 2, 3 and 4). The skin at this time was much improved but was still edematous about the ankles. The serum calcium was 11.20, inorganic phosphorus 4.1 and nonprotein nitrogen 45.1 mg. per hundred cubic centimeters on July 23, 1945. *The twenty-four hour urinary calcium at the same time was 405 mg.* Polyuria and albuminuria were still present.

CASE 2.—A white man aged 39, admitted to a hospital on Aug. 29, 1945 because of low back pain, nausea, vomiting and generalized aching, stated that he developed a backache two and a half years previously, during an attack of influenza, which had persisted to some degree ever since. He had been examined repeatedly by numerous physicians. In 1944 the patient was admitted to a second hospital, where the backache was ascribed to fibrositis and nonspecific prostatitis. At that time the blood pressure was 132/72 and he weighed 135 pounds (61 Kg.). The blood urea was 26 mg. per hundred cubic centimeters.

Various forms of therapy were tried, including typhoid vaccine, thyroid, oral calcium, physical therapy, osteopathy, braces and vitamins. Previous roentgenograms of the teeth and spine were negative.

TABLE 2.—*Composition of Joint Exudate and Exfoliated Skin in Patient 1, with Ertron Poisoning*

	Aspirated Fluid (3/8/45)	Exfoliated Skin (March 1945)
Calcium	1.80 Gm. per 100 cc.	3.08 mg. per 100 Gm.
Phosphorus	0.778 Gm. per 100 cc.	3.50 mg. per 100 Gm.
Protein	3.22 Gm. per 100 cc.	
Nonprotein nitrogen	65.0 mg. per 100 cc.	

In the spring of 1945 the patient took one capsule daily of vitamin D (50,000 units) for fifty days. In June he started Ertron capsules, taking six capsules per day, 250 capsules in all, and had in addition one intramuscular injection of 500,000 units. Three weeks prior to admission he stopped this medication because of the onset of nausea, vomiting and extreme restlessness. His teeth became extremely sensitive to temperature and sharp shooting pains developed in both legs. An old bursitis of the left shoulder flared up. His eyes became bloodshot, and a maculopapular eruption appeared on his face.

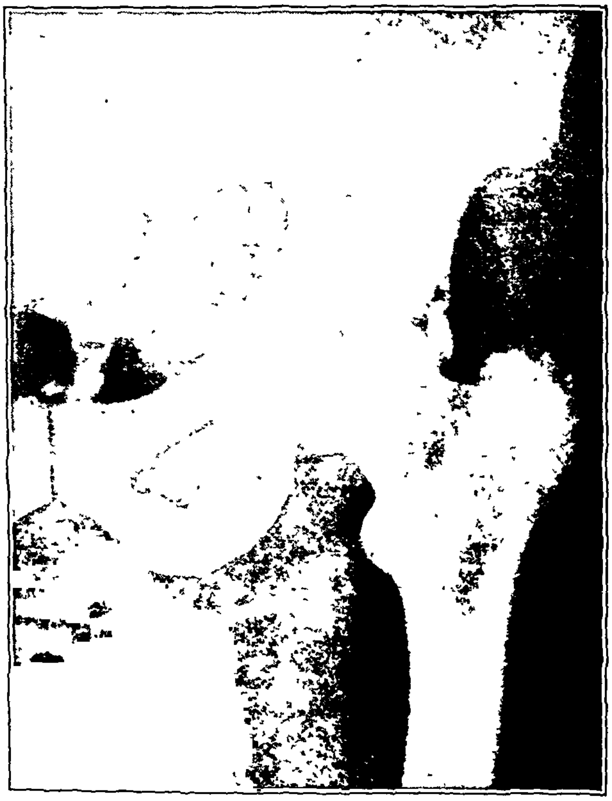

Fig. 4 (case 1).—Left side of pelvis in February 1945, six months after ingestion of Ertron and a high milk diet had been discontinued.

He also complained of daytime frequency of urination and nocturia, and at the time of admission he had been unable to sleep for five days and nights despite sedation.

On physical examination the weight was 136 pounds (61.7 Kg.), the blood pressure was 155/85 and the vessels of the conjunctivas were much injected. The heart, lungs and abdomen were normal. Tendon and superficial reflexes were present. Spasm of the sacrospinalis muscle was evident. The prostate was small and indurated. The prostatic secretion contained some leukocytes, and there was a residual urine of 60 cc. No abnormalities of the teeth or skeleton could be demonstrated by x-ray. The electrocardiogram showed left axis deviation but was otherwise normal. The laboratory findings obtained at this time and on a subsequent visit to the hospital are shown in table 3. He was diagnosed as having renal insufficiency, probably due to excessive Ertron medication, chronic myositis of the sacrospinalis muscle and chronic prostatitis.

The patient remained in the hospital seven days and was extremely restless despite sedation. The body temperature remained subnormal throughout his stay. The blood pressure decreased to 134/80 before the patient was discharged. He was instructed in the selection of a diet low in calcium and phosphorus and encouraged to maintain a high fluid intake.

On his next admission (Oct. 17, 1945) there were signs of definite improvement. He no longer had insomnia, pains in the back and legs, hypersensitive teeth or extreme restlessness. His appetite was better, there was no nausea, and the patient stated that his head seemed much clearer. Physical examination was essentially negative except for the persistence of some congestion of the conjunctival vessels. The laboratory data obtained at this time (table 3) gave further evidence of this improvement.

EFFECT OF ERTRON ON CALCIUM EXCRETION

The effect of Ertron on the calcium balance of a patient with arthritis was also studied. This case history and procedure follows:

CASE 3.—A white boy aged 9 years, weighing 49 pounds (22 Kg.) had had rheumatoid arthritis five years at the time this study was made. When 4 years of age (in the fall of 1932) he had a sudden onset of pain in the right ankle associated with redness, limitation of motion and fever (104-105 F. daily for five months). The fever and redness of the joints subsided, but enlargement and limitation of motion persisted. During the succeeding four and a half years other joints became involved. At the time of this study he had limitation of motion and enlargement of the joints of the fingers, toes, wrists, elbows, ankles, knees and hips. X-ray studies showed considerable rarefaction of the bones in the involved areas.

TABLE 3.—*Laboratory Findings in Patient 2, with Renal Insufficiency Caused by Ertron Ingestion**

	July 1944	August 1945	October 1945
Blood pressure:			
Systolic (mm. Hg)	132	155	112
Diastolic (mm. Hg)	72	85	75
Basal metabolic rate (%)		..	−12

Hemoglobin (Gm.)		12.0	13.0
R. B. C. (million/cu. mm.)		3.85	3.94

* Ertron administration was stopped a few days prior to the determination made in August 1945 and not resumed.

† Bodansky units per 100 cc. serum.

During the time of the metabolic study his clinical condition remained unaltered until Ertron administration, together with a high calcium diet, was instituted. During the second collection period on this regimen the patient complained of joint pains, loss of appetite and frequency of urination. At this time there was puffiness about the eyes and albuminuria. The symptoms and albuminuria disappeared approximately one week after Ertron administration was discontinued.

The low calcium diet and metabolic procedure were similar to that described by Bauer and Aub.[11] The low calcium diet provided 1,600 calories per day and contained, by analysis, 0.2 Gm. of calcium. The high calcium diet was the same with the addition of 1 quart of milk daily and a suitable reduction in calories from other sources. All control data were obtained before treatment with Ertron was instituted. Each five day metabolic period was preceded by one week on the diet before collection of excreta was begun. The studies consisted of two metabolic periods on each diet. Ertron medication (100,000 units daily) was begun one week before the collection of excreta and continued uninterrupted throughout the period of observations of its effect, while the patient was on a low and a high calcium intake. The results of this study are shown in table 4.

TABLE 4.—*Effect of Ertron on Calcium Balance in a Child with Rheumatoid Arthritis*

		Low Calcium Diet, 0.2 Gm. Daily		High Calcium Diet, 1.4 Gm. Daily	
Case 3		1st Period Mg./Period	2d Period Mg./Period	1st Period Mg./Period	2d Period Mg./Period

Excreta collected in five day periods.

COMMENT

The 2 patients apparently suffering from toxic symptoms due to Ertron had many findings in common, including Ertron ingestion, renal insufficiency, a high milk consumption, polyuria, albuminuria, lassitude, weakness, anorexia, eosinophilia, anemia, enlargement of the prostate, bursitis, skin eruption, involvement of the conjunctiva and subnormal body temperature. It is beyond the scope of this paper to discuss these findings in any detail. The symptoms of vitamin D poisoning have been well described by others.[12] Slocumb[6] reported an elevation of the blood urea in a patient receiving vitamin D who had no symptoms of poisoning. Once manifestations of toxicity have occurred, they may persist for some time after vitamin D administration has been discontinued. The prolonged effects of vitamin D poisoning are well illustrated in cases 1 and 2 as in cases reported by others.[2]

Metastatic calcification of the soft tissues is one of the characteristic findings in animals poisoned with vitamin D, and the kidney is frequently the site of these deposits. Ashford[13] demonstrated that metastatic calcification, produced experimentally in rabbits, underwent resorption after vitamin D administration was discontinued. Metastatic calcification was present in 1 of the patients in the report of Danowski, Winkler and Peters and was a conspicuous finding in the first patient in this report. This patient, though maintained on a low calcium-low phosphorus diet has continued to excrete approximately 400 mg. of urinary calcium daily as judged by repeated calcium determinations during the past eight months. It is an interesting finding that the calcium-rich viscid fluid aspirated from the subdeltoid bursa of this patient had the same calcium-phosphorus ratio as normal bone (2.30) [14] (table 2). The calcium and phosphorus content of desquamated skin are also included in this table. No comparable skin sample from patients with any other condition has been obtained for analysis.

[13] Ashford, C. A.: The Phosphorus Distribution in Blood and the Calcium and Phosphorus Excretion During Hypervitaminosis D, Biochem. J. 24: 661, 1930.

Numerous studies have demonstrated that the absolute as well as the relative amounts of calcium and phosphorus in the diet influence the toxicity of vitamin D.[15] Both of the intoxicated patients presented in this report gave as a part of their history that they consumed from 1 to 2 quarts of milk daily. One of the patients of Danowski and his associates was reported as drinking a quart of milk daily. Freeman and Farmer [16] showed that a given dose of vitamin D may or may not produce hypercalcemia in dogs, depending on their calcium intake. It has also been shown that dogs given large doses of vitamin D manifest a more severe and prolonged hypercalcemia than normal dogs following the oral [15] or intravenous [17] administration of calcium. In view of the experimental evidence, it is surprising to find that little attempt has been made to control the calcium intake of patients receiving large doses of vitamin D. Some of the patients have been encouraged to drink liberal amounts of milk.[18] It is reasonable to suppose that the high calcium and phosphorus intake which a quart or more of milk daily provides contributed materially to the toxicity of Ertron taken by the patients who were the subjects of the present report. It has also been shown [19] that a liberal milk intake, as well as other foods rich in phosphorus, have an adverse effect on the blood chemistry, symptomatology and roentgenologic findings of patients with renal insufficiency.

The metabolic study in case 3 revealed an increase in the urinary excretion of calcium while the patient was receiving Ertron both on the low and on the high calcium diets. Ertron reduced the fecal excretion of calcium on the low calcium diet and increased the fecal loss of calcium while the patient was on a high calcium diet. Studies on animals have shown that large doses of vitamin D reduce calcium retention, as evidenced by decalcification of the bones, even to the point of causing spontaneous fractures.[20] Ertron reduced calcium retention slightly on the low and definitely on the high calcium diets (table 4). While this patient was on a high calcium diet and receiving Ertron he developed an albuminuria which had never been present before and which cleared up one week after Ertron administration was discontinued. The serum calcium of this child was not elevated at the end of the metabolic study. These findings are evidence that an increased urinary calcium excretion and conditions favorable to the deposition of calcium in the kidney may precede, and need not be accompanied by, hypercalcemia. These considerations make apparent how renal failure might occur without having been preceded by a hypercalcemia. These results show clearly that the kidneys of a person taking excessive doses of vitamin D may be required to excrete much more calcium than would normally be the case, particularly when the calcium intake is high. An increased urinary excretion of inorganic phosphate usually occurs also in hypervitaminosis D.[21] The increased concentration of calcium and phosphate in the fluids that are in contact with the kidney would provide favorable circumstances for calcification of this organ. That the organ need not be previously damaged to undergo calcification during hypervitaminosis D is indicated by the experimental study of Ham [22] as well as by the work of many other workers.

According to a report prepared by a committee of the American Rheumatism Association [23] the therapeutic effects of large doses of vitamin D are of doubtful value in the treatment of arthritis. The whole question of vitamin D therapy in the treatment of arthritis has been thoroughly discussed by Comroe.[24] The therapeutic objectives to be achieved by large doses of vitamin D have not been clearly formulated by any of its exponents. The results obtained in case 3 indicate that large doses of Ertron may reduce calcium retention by the body. This effect would seem to be undesirable for patients who already have a rarefaction of the skeleton. Irrespective of the merits of vitamin D in the treatment of arthritis, it remains an established fact that large doses are toxic to human beings and animals. That Ertron is no exception to this statement is evidenced by the following facts: (*a*) Both patients in the present report and 1 patient in the report by Danowski and his associates showed toxic manifestations of a serious nature associated with an altered calcium metabolism while taking Ertron, and these manifestations declined after this medication was discontinued; (*b*) Ertron was shown to be a potent hypercalcemic agent in dogs by McChesney and Messer; [5] (*c*) Ertron is a potent source of vitamin D, according to the claims of the manufacturer.[25]

It is beyond the scope of this paper to discuss the toxicity of sterols, other than vitamin D itself, that may contribute to the toxicity of vitamin D preparations. It has been shown[26] that pure, crystalline vitamin D (calciferol) is toxic and that hypercalcemia is associated with toxic manifestations from this substance. A hypercalcemia accompanied by a significant increase in the ionic calcium content of the blood, from any cause, is usually associated with manifestations of toxicity. If elevation of the blood calcium persists for a sufficient length of time, renal failure is the inevitable consequence. Instances of toxicity from vitamin D in the absence of hypercalcemia may be due to hyperphosphatemia which occurs secondary to renal failure or because the blood inorganic phosphorus of some species (e. g. the rabbit) is readily elevated by large doses of vitamin D. Depression of the hypercalcemia and elevation of the serum inorganic phosphorus and nonprotein nitrogen were shown by Taylor and his associates[27] to be characteristics of advanced irradiated ergosterol poisoning in dogs. These authors as well as others[28] have pointed out the decided similarity of the toxic manifestations caused by solution of parathyroid and by vitamin D. Collip[29] has shown that renal insufficiency, accompanying experimental hyperparathyroidism in dogs, reduces the hypercalcemia while the inorganic phosphorus and nonprotein nitrogen increase to values far above normal. More recently, Neufeld and Collip[30] have shown that hypercalcemia cannot be produced by solution of parathyroid administered to dogs with a hyperphosphatemia.

CONCLUSION AND RECOMMENDATIONS

The use of large doses of vitamin D in the treatment of arthritis is a dangerous practice which may do the patient harm. The use of repeated large doses of vitamin D for any therapeutic purpose should be accompanied by appropriate tests, performed at regular intervals, to determine the state of calcium metabolism and kidney function. The maintenance of a relatively constant calcium and phosphorus intake simplifies this problem. The following tests are suggested as appropriate for this purpose: blood nonprotein nitrogen or urea, serum calcium and inorganic phosphorus; the twenty-four hour urinary excretion of calcium with the patient maintained on a low calcium diet for no less than two days prior to the collection of urine; qualitative test for the presence of albumin in the urine; concentration-dilution test and phenolsulfonthalein excretion as measures of tubular function. It follows that such tests should be applied to patients prior to the administration of large doses of vitamin D and that evidence of impaired kidney function should be considered as a contraindication to this treatment. We do not mean to imply that these tests, though the results should be consistently within the normal range, give one assurance that metastatic calcification is not promoted by this treatment. However, gross impairment of the kidneys, such as was present in cases 1 and 2 of this report, could certainly have been averted if the tests mentioned had been applied routinely in conjunction with the Ertron therapy. It is suggested that the history taken on every patient suspected of having renal disease should include questions intended to determine whether or not the patient has ever taken large doses of vitamin D.

SUMMARY

1. Renal insufficiency occurred in 2 patients receiving doses of Ertron such as are used currently in the treatment of arthritis.

2. A decreased calcium retention and an increased urinary excretion of calcium occurred in a child with rheumatoid arthritis who was given 100,000 units of Ertron daily.

3. Large doses of vitamin D from any source are potentially toxic, and this toxicity can be explained as due to its effect on calcium and phosphorus metabolism and kidney function.

EFFECT OF PENICILLIN ON COURSE OF EARLY SYPHILIS

MAJOR WILLIAM LEIFER
and
CAPTAIN SAMUEL P. MARTIN
Medical Corps, Army of the United States

In early syphilis prompt diagnosis and initiation of treatment decrease opportunity for dissemination of infection and increase probability of cure. The dual effectiveness of penicillin against Treponema pallidum and Neisseria gonorrheae has complicated the problem of the early diagnosis of syphilis. The incubation period of gonococcic urethritis is usually three to five days and exceptionally one to two weeks;[1] the incubation period of primary syphilis is ten to ninety days, with an average of three weeks.[2] Consequently, in simultaneous infections the urethritis may be treated with penicillin while the patient is in the incubation stage of syphilis. For various reasons also treatment may be given when a chancre is already present: the lesion may be missed because of its unusual location, as in intrameatal, intraurethral, extragenital or cervical chancres; the chancre may be concealed by inflammatory phimosis or it may be regarded as a banal lesion; and, in cases in which syphilis is suspected, the diagnosis may seemingly be excluded by one or more negative dark field examinations or serologic tests for syphilis.

When early syphilis is treated with 60,000 to 1,200,000 units of penicillin in seven and one-half days, the disappearance of treponemes from lesions, the healing of lesions and the reversal of serologic tests are practically the same with all dosages. The chief difference is in the incidence of relapse, which increases as the dose decreases and is prohibitive with the smaller doses of 60,000 to 300,000 units.[3]

In uncomplicated gonococcic urethritis the usual dose of penicillin is 100,000 units given over a period of nine to twelve hours; less often 200,000 to 300,000 units is administered in twenty-seven to forty-two hours or in a single injection in beeswax-peanut oil.[4] Since

the effects of these dosage schedules on early syphilis are not definitely known, it seemed desirable to review 7 cases of simultaneous infection observed in our clinic and to evaluate 8 cases collected from the literature. That the problem is more than academic is shown by the observations of Kemp and Shaw,[5] who found primary syphilis associated with gonorrhea in 1.4 per cent of 500 males and 3.0 per cent of 500 females.

REPORT OF CASES

For the sake of convenience, the case reports are numbered in sequence: Cases 1 to 7 were observed in our clinic, and cases 8 to 15 have been collected from the literature.

Case 1.—A white soldier aged 34 was exposed on April 24, 1945 and reported with a urethral discharge on May 3. A diagnosis of gonococcic urethritis was established, and on the same day the patient was given four intramuscular injections of 25,000 units of penicillin in saline solution at three hour intervals. Reexaminations were made at weekly intervals for the next three weeks; the patient remained clinically well, and bacteriologic studies for N. gonorrheae were negative. On May 27, thirty-three days after the last exposure, the patient developed an ulcer in the coronal sulcus of the penis; dark field examination revealed Treponema pallidum, and the Kahn test of the blood was negative.

Case 2.—A white soldier aged 32 was exposed on Nov. 24, 1944 and developed a urethral discharge on December 3. On December 9, after the diagnosis of gonococcic urethritis was confirmed, he was given 100,000 units of penicillin in saline solution in four intramuscular injections of 25,000 units at three hour intervals. On Jan. 13, 1945, fifty days after the last exposure, the patient developed a penile ulcer; dark field examination revealed Treponema pallidum, and the Kahn test of the blood was negative.

Case 3.—A Negro soldier aged 21 received 100,000 units of penicillin for gonococcic urethritis on Nov. 14, 1944. No penile lesion was present and the serologic test for syphilis was negative. The last sexual exposure occurred approximately seven days before the appearance of the urethritis, and the patient denied any subsequent exposure. At no time during the observation period was a penile lesion or an eruption observed by the patient or the physician. A routine Kahn test of the blood was performed on December 18, and it was found positive (4 units); Kahn tests on Dec. 28, 1944 and Jan. 17, 1945 were also positive and showed an increase from the original titer of 4 units to 160 units. On January 17 the patient was again examined thoroughly and no lesions of the skin and mucous membranes were found, the only abnormality being a moderate generalized lymphadenopathy, most pronounced in the inguinal regions.

Case 4.—A white soldier aged 24 was seen on May 31, 1945 with a urethral discharge and a small, nonindurated erosion on the mucous surface of the prepuce. The last sexual exposure had occurred on May 8. The smear and culture of the urethral discharge established the diagnosis of gonococcic urethritis; a single dark field examination and Kahn and Wassermann test of the blood were negative. On June 1 the patient was given 100,000 units of penicillin intramuscularly in four equal doses at three hour intervals. The patient was not seen again until August 25, when he returned with a large punched-out, indurated ulcer of the external surface of the prepuce and a generalized secondary syphilitic eruption. The ulcer had been present for twenty-five days but the patient had been reluctant to report it. The original erosion of the prepuce was completely healed. The dark field examination revealed Treponema pallidum, and the Kahn and Wassermann tests of the blood were positive. There had been no sexual exposure since May 8, and the recurrent (?) chancre had appeared on August 1, that is, eighty-five days later.

Case 5.—A Negro soldier aged 21 was given a single intramuscular injection of 100,000 units of penicillin in beeswax-peanut oil for gonococcic urethritis. Prior to treatment a small, nonindurated excoriation was noted at the urethral meatus, but this was attributed to the profuse discharge and no dark field examination was made. There was no enlargement of the inguinal lymph nodes. About six hours after the penicillin injection the patient complained of severe chilly sensations and feverishness, and his temperature was found to be 103.8 F. Primary syphilis was immediately suspected, and it was observed that the excoriation at the meatus had increased in size. A dark field examination was made at once, with negative results. Dark field examinations were repeated daily thereafter, and on the third day following treatment Treponema pallidum was demonstrated. The serologic tests for syphilis were positive.

Case 6.—A white soldier aged 35 was last exposed on July 23, 1945 and on August 17 he noted a lesion of the mucous surface of the prepuce. When he reported to his clinic on August 20 there was a balanitis and purulent discharge, and, without requisite laboratory examinations, 100,000 units of penicillin was given intramuscularly in divided doses. About four hours after the first injection the patient developed fever and generalized aching pains, and his temperature was found to be 103.2 F. The fever was erroneously interpreted as recurrent malaria, although no plasmodia were present in the blood smear. The patient was referred to the Venereal Disease Clinic on August 23 and was found to have a large healed chancre of the prepuce, a secondary syphiloderm and, repeatedly, strongly positive serologic tests for syphilis.

Case 7.—A white soldier aged 22 was treated oversea on July 3, 1945 for gonococcic urethritis with 100,000 units of penicillin administered over a period of eight hours. The patient stated that there were no genital lesions and no inflammatory phimosis when he was treated. About four to five hours after the initial dose of penicillin the patient developed fever, chilly sensations and generalized aching pains; subsequently there was severe headache, and the temperature rose to 105.8 F. The patient was hospitalized, but no cause for the fever was found, and the temperature became normal within twenty-four hours. The serologic tests for syphilis were negative. On August 11 the patient noted a generalized eruption, and he was referred to the Venereal Disease Clinic. He was found to have a generalized secondary syphilitic eruption, the dark field revealed Treponema pallidum, and the serologic tests were strongly positive for syphilis.

Case 8.—Ricchiutti[6] reported the administration of 100,000 units of penicillin in saline solution to a patient with gonococcic urethritis and inflammatory phimosis. Following the second injection of 20,000 units the patient's temperature rose to 101.4 F. and the prepuce became more swollen. A dorsal slit was performed and an ulcer of the sulcus was exposed. Dark field examinations were negative; the Kahn test of the blood, which was negative at first, became positive sixteen days after the treatment with penicillin.

Case 9.—Carpenter[7] reported that a patient received 50,000 units of penicillin in saline solution in five intramuscular injections of 10,000 units twenty-two days after the last exposure. The patient developed two clinically typical but dark field negative penile ulcers on the forty-eighth day after exposure, and it was not until the seventy-second day that the diagnosis of syphilis was established, when the serologic tests became positive.

Case 10.—Boyd, Wagner and Hewson[8] published a report of a case in which urethritis and epididymitis were associated with penile ulcers. Since the dark field examination and the Kahn test of the blood were negative, treatment was instituted and 80,000 units of penicillin given. The penile ulcers healed but recurred about twenty-seven days later at the original site. The Kahn tests of the blood remained negative, but some four weeks later Treponema pallidum was demonstrated in the lesions.

Case 11.—Canizares[9] reported a similar case in which the dark field examination and Kahn test of the blood were negative. Both the urethritis and the penile lesion responded to 50,000 units of penicillin. Eighteen days following treatment the penile ulcer recurred, and five days after that the dark field revealed Treponema pallidum.

Case 12.—Baier and Pincus[10] recorded a case in which the penile lesion was not called to the attention of the physician until 100,000 units of penicillin had been given for gonococcic urethritis. Several dark field examinations and Kahn tests of the blood were negative. The penile ulcers healed and recurred about a month later. Dark field examinations remained negative, but repeated serologic tests for syphilis were positive.

Case 13.—Hailey[11] treated a patient for gonococcic urethritis with 100,000 units of penicillin only after repeated dark field examinations of the penile lesions and Kahn tests of the blood had been negative. The penile ulcers healed and recurred about a month later. Dark field examinations remained negative, but repeated serologic tests for syphilis were positive.

Case 14.—Sternberg and Turner[12] recorded an instance in which 100,000 units of penicillin was given before a dark field examination was made of a penile ulcer. The following day the dark field examination was negative and the ulcer healed rapidly. "Six weeks later a typical dark field positive chancre appeared in the same location. The patient denied further sexual exposure."

Effect of Penicillin on the Syphilitic Infection, and Number of Days After Penicillin Treatment That a Positive Diagnosis of Syphilis Was Established

7		39	39
8		..	16

Case 15.—Shafer and Zakon[13] observed a patient who had received elsewhere 100,000 units of penicillin for gonococcic urethritis at the same time that he had a penile lesion. Apparently no dark field examination of the penile lesion had been made, but the Kahn test of the blood had been negative. Two months later the patient was found to have a recurrence of the penile lesion and a generalized secondary eruption; the Kahn and Wassermann tests of the blood were positive.

The pertinent data in the 15 cases are presented in the accompanying table. It is apparent that the diagnosis of syphilis was established in every case, by appropriate laboratory measures, less than ninety days after penicillin was administered for gonococcic urethritis. The longest period was eighty-five days, in case 4, but this was only because of failure to return for observation at the usual intervals following treatment.

COMMENT

The doses of penicillin used for gonococcic urethritis may have several potential effects on coincidental early syphilitic infection. When given during the incubation period it is conceivable that the syphilitic infection may be cured; but it is more likely that a chancre will appear, perhaps after a prolonged period of incubation, or that a completely symptomless infection will result. Treatment during the primary stage of syphilis may be anticipated to heal the lesion prematurely, following which the lesion may recur, the disease may be rendered asymptomatic or a secondary eruption may appear; or the action of the penicillin on the treponemes may evoke a febrile Herxheimer reaction.

Of the group of 15 patients evaluated, 4 received 50,000 or 100,000 units of penicillin while in the incubation period (cases 1, 2, 3 and 9). Clearly the infection was cured in none, for all 4 cases progressed; 3 went on to the development of a chancre, and the fourth had a symptomless infection. The chancre appeared in the 3 cases approximately 33, 48 and 50 days after the last sexual contact. While these incubation periods are definitely prolonged beyond the average of 21 days, they are well within the upper limit of 90 days. In the fourth case (case 3) no clinical manifestations of syphilis appeared at any time, and the diagnosis was made only by repeatedly positive serologic tests. Prolonged incubation periods, and symptomless infections—Moore[14] estimates symptomless infections at 20 per cent in males and 33 per cent in females—occur even in the untreated syphilitic patient. It will require study of large groups of patients to determine whether subcurative doses of penicillin cause a significantly increased incidence of these clinical phenomena.

In the 11 patients treated during the primary stage of syphilis, the chancres tended to heal and to recur later in most instances. Several developed secondary syphilitic lesions before the disease was recognized. In all there was consequent delay in the diagnosis of syphilis: disappearance of surface treponemes rendered dark field diagnosis difficult, if not impossible, so that in many cases positive serologic tests had to be awaited. However, none of the cases could be construed as examples of relapsing syphilis in the sense that the patients had passed through the secondary stage and then developed mucocutaneous or visceral forms of relapse. Hough[15] has recalled the high incidence of neurologic and other types of relapse observed in the early days of arsphenamine therapy, when one or two doses were believed curative, and he has suggested that a similar situation may arise from inadequate treatment with penicillin. This possibility must be kept in mind, particularly in patients treated for gonococcic urethritis, the doses of penicillin being grossly inadequate for syphilis.

A febrile reaction occurred in 4 cases (5, 6, 7 and 8), and this was interpreted as a systemic Herxheimer reaction due to the treponemicidal action of penicillin. Herxheimer reactions are common in early syphilis with both arsenic and penicillin, and they may be systemic and/or focal. The focal symptoms and signs consist of edema of the chancre and adjacent tissues; pain and swelling in enlarged regional lymph nodes, usually the inguinals, and exaggeration of secondary syphilitic lesions. Of a series of 53 patients with primary syphilis treated at this hospital[16] with 20,000 units of penicillin intramuscularly at three hour intervals, 8 had no fever; 27 had fever from 100 to 102 F., and 18 had temperatures higher than 102 F. Thus, 85 per cent had a febrile Herxheimer reaction, which appeared four to eight hours after the initial dose of penicillin. The high incidence in this group is attributed in part to the careful search that was made for fever, by the recording of rectal temperature at two hour intervals. With the purified penicillin now available, fever as a toxic manifestation, due to contained pyrogens, is extremely rare. We have not observed it among hundreds of patients treated with penicillin for uncomplicated gonococcic urethritis.

There can be little doubt, from the evidence presented in this paper, that subcurative doses of penicillin modify the course of early syphilis. The modification evinced itself in several different ways. There appeared to be prolongation of the incubation period in 3 cases, in 1 the infection was symptomless and in the remaining 11 there was suppression and concealment of the syphilitic lesions. The tendency was to make the disease insusceptible of diagnosis for a longer period than is the rule when it pursues its natural biologic course. Consequently there was greater opportunity for dissemination of the disease, and reduced probability for cure of the patient. However, the fact of greatest importance, which cannot be overemphasized, is shown clearly in the table. In all 15 cases the diagnosis of syphilis was definitely established less than ninety days after penicillin treatment of gonococcic urethritis. It would seem, therefore, that clinical and serologic observation for ninety days from the date of treatment would suffice to detect all but the most exceptional cases of syphilis: this is the present policy of the United States Army.[17]

Every patient treated for gonococcic urethritis should be informed that a concomitant early syphilitic infection may coexist; the patient should be urged to report immediately in the event that a genital lesion or cutaneous eruption appears and should be warned against sexual intercourse until the observation period is completed. The management of the case should include (1) a careful pretreatment inspection for lesions, with repeated dark field examinations, (2) a serologic test for syphilis at the first visit, repeated at least monthly for ninety days, and (3) the recording of the temperature at two hour intervals, during the penicillin therapy, to detect a low grade febrile Herxheimer reaction.

SUMMARY

Of 15 patients treated with 50,000 or 100,000 units of penicillin for gonococcic urethritis while suffering from a concomitant early syphilitic infection, the penicillin appeared to prolong the incubation period of primary syphilis in 3, the syphilitic lesions were suppressed and concealed in 8 and a febrile Herxheimer reaction occurred on the day of penicillin therapy in 4.

In every case the diagnosis of syphilis was proved by demonstration of treponemes in the lesions, or repeatedly positive serologic tests, in less than ninety days after penicillin was administered: on the basis of this, clinical and serologic observation for three months is recommended for all patients.

Clinical Notes, Suggestions and New Instruments

RECOVERY FROM PULMONARY MONILIASIS FOLLOWING SERUM THERAPY

JOSEPH S. HIATT JR., M.D.,* and DONALD S. MARTIN, M.D.
Durham, N. C.

This case of severe pulmonary moniliasis is presented because of the unusual immunologic findings and because of the dramatic recovery which followed the administration of immune serum.

REPORT OF CASE

History.—A. T., a white woman aged 44, married, a housewife, was admitted to Duke Hospital on July 8, 1940 with the chief complaints of malaise, fatigue, cough and loss of weight for the preceding two months. The family history was negative except that one sister had bronchial asthma.

Two years before admission the patient had been ill for five months with symptoms of malaise, fever and cough productive of one-half cupful of white foamy sputum. During her illness she had lost 10 pounds (4.5 Kg.) in weight and was told by her physician that she had a pulmonary infection. She recovered satisfactorily on iodide therapy.

The present illness began two months before admission with the development of symptoms similar to those of her previous illness, namely malaise, fatigue and a weight loss of 15 pounds (6.8 Kg.). She again had a cough, productive of 1 tablespoon of mucoid, odorless sputum daily. She noted afternoon temperature elevation as high as 39.4 C. (103 F.) but had no frank chills, chest pain, hemoptyses or night sweats. Iodides were administered by her physician but had to be discontinued because of the appearance of a pustular eruption on the face. Three weeks prior to admission she was admitted to another hospital, where she received, over a ten day period, a course of one of the sulfonamides with some subjective improvement.

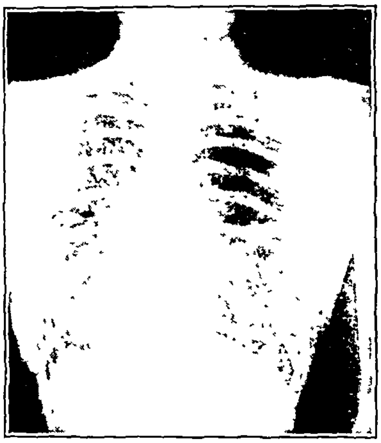

Fig. 1.—Appearance on admission, July 8, 1940.

Physical Examination.—The temperature was 38 C. (100.6 F.), pulse rate 92, respiratory rate 22 and blood pressure 120/70. The patient was emaciated and appeared to be chronically ill but in no acute cardiorespiratory distress. There was a brownish pigmented area over the nose extending to the cheeks, producing a "butterfly" appearance. The tongue was somewhat smooth and reddened, with marginal papillary atrophy. The chest was asthenic, with dulness at the left base and increased tactile and vocal fremitus over this area. Coarse moist rales were present throughout both lung fields. There was no cyanosis and no clubbing of the fingers. The remainder of the examination was normal.

Accessory Clinical Findings.—The hemoglobin was 9.3 Gm., or 60 per cent (Sahli), and the erythrocyte count was 3,920,000 per cubic millimeter. The white blood cell count was 19,000 per cubic millimeter and the erythrocyte sedimentation rate was 31 mm. per hour corrected. Examination of the fresh blood showed anisocytosis, poikilocytosis and the presence of both

[17] Treatment of Gonorrhea, United States War Department, Technical Bulletin (TB Med 96), Washington, D. C., Government Printing Office, 1944.

From the Departments of Medicine and Bacteriology, Duke University School of Medicine.

A part of the cost of this investigation was borne by a grant from the John and Mary R. Markle Foundation.

microcytes and macrocytes. The blood Wassermann and Kahn tests were negative. Urine and stool examinations showed no abnormalities.

Candida albicans was isolated from the sputum on numerous occasions. Repeated examinations of concentrated sputum and gastric washings were negative for tubercle bacilli, and guinea pigs inoculated with concentrated sputum remained well. Skin tests were negative to old tuberculin in all dilutions up to 1 mg.

Fluoroscopic and x-ray examinations of the chest showed diffuse densities throughout both lung fields, most likely due to infiltration, with lesions at the left base somewhat coalesced. The x-ray findings were interpreted as being consistent with a diagnosis of a diffuse bronchomycotic infection (fig. 1).

A skin test with a vaccine prepared from a stock culture of candida albicans was negative, and no agglutinins for the fungus could be demonstrated in the serum of the patient.

Course in the Hospital.—The patient continued to be very ill with anorexia, temperature spiking daily to 40 C. (104 F.) and cough productive of white mucoid sputum, which varied in amount from 1 tablespoon to ½ cup every twenty-four hours. The patient was given all the accessory vitamins, iron and various antianemic measures. Intravenous glucose and parenteral vitamins were administered as supportive measures.

Since the patient was known to be sensitive to iodides, gentian violet therapy was begun on July 18, 1940, when she received 2 mg. per kilogram of body weight of the drug intravenously. Subsequently she was given two injections of gentian violet 3 mg. per kilogram and six injections of 4 mg. per kilogram, the last on August 28. After each of the injections the patient complained of substernal oppression, dyspnea and a sensation of choking and smothering, and exhibited decided cyanosis. Gentian violet therapy had to be discontinued because of the symptoms cited and the thrombosis of all accessible veins.

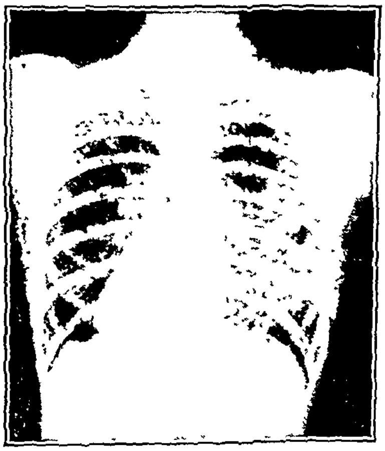

Fig. 2.—Progress of disease, September 16.

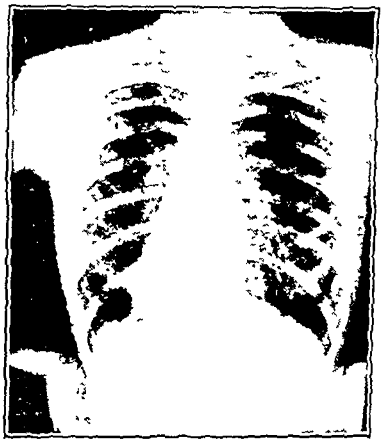

Fig. 3.—Remarkable clearing with immune serum therapy, October 22.

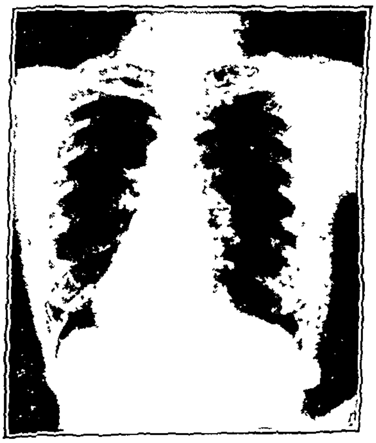

Fig. 4.—Complete clearing, March 31, 1941.

An x-ray of the chest made on September 16 showed a considerable increase in the extent and density of the widespread pulmonary lesions (fig. 2).

The patient coughed up a small amount of bright red blood on August 22. Because of failure to improve on gentian violet therapy, it was decided to try iodides. After negative skin tests and patch tests to potassium iodide, the drug was given orally in an initial dose of 20 drops and the dosage increased 10 drops a day. The drug had to be discontinued on the fifth day because of a severe ioderma involving the face. A transfusion of 500 cc. of citrated blood was given without reaction on September 11.

The patient was again skin tested with an autogenous vaccine of Candida albicans isolated from her sputum, and the reaction was negative. No agglutinins for the fungus could be found in the patient's serum.

Because of a previous experience with a patient suffering from North American blastomycosis[1] who had the same immunologic findings, i. e. negative skin test to Blastomyces vaccine, a negative complement fixation test and a positive immediate reaction to an anti-Blastomyces rabbit serum, it was decided to test this patient with the serum of a rabbit which had been previously immunized with Candida albicans. Injection of 0.1 cc. of the anti-Candida albicans rabbit serum resulted in the formation of a wheal with pseudopodia surrounded by a 5 cm. zone of erythema. Hypersensitivity to rabbit serum was excluded by injection of 0.1 cc. of normal rabbit serum, to which there was no reaction.

The immunologic findings were interpreted as indicating that the patient was flooded with an excess of the fungus antigen, which inhibited both the agglutination reaction and the skin test to the vaccine. The findings suggested also that the administration of immune serum might neutralize the hypothecated excess antigen, permitting the patient's own immune mechanism to become effective.

The patient was given immune anti-Candida albicans rabbit serum subcutaneously, beginning with 0.1 cc. of a 1 : 10 dilution, and the dose was increased by 0.1 cc. daily until a dose of 0.9 cc. was reached. The desensitization series was repeated twice (beginning October 3 and completed October 26). Following serum therapy there was a total remission of all subjective symptoms. An x-ray of the chest taken on October 22 showed remarkable clearing (fig. 3).

On October 24 an agglutination test showed agglutinins for Candida albicans to be present in a 1 : 80 dilution of serum. The skin test to vaccine became slightly positive. Retesting with immune rabbit serum gave a slight reaction, which was no greater than that of the normal rabbit serum control. This was interpreted as a negative immune serum test.

The patient was discharged on Nov. 2, 1940 feeling well and entirely symptom free.

Follow-Up.—X-rays of the chest made on Dec. 12, 1940 and on March 3, 1941 were interpreted as essentially normal (fig. 4). The skin test to Candida albicans has remained negative but the agglutinins were still positive in a 1 : 80 dilution. An electrocardiogram showed no abnormalities.

Subsequently the patient developed mild asthmatic episodes and was found to be sensitive to extracts of Alternaria and Hormodendrum and to oidiomycin. At the present time her asthma is being controlled by desensitization with extracts of these fungi. Several recent cultures from her nose and throat have shown no growth of Candida albicans.

SUMMARY

A patient with severe pulmonary moniliasis showed evidence of an excess of antigen in the tissue and absence of circulating antibodies. She failed to improve with the usual methods of treatment but made a dramatic recovery after the administration of small amounts of immune rabbit serum.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. Howard A. Carter, Secretary.

RADIUM

ARTHUR U. DESJARDINS, M.D.
and
MARVIN M. D. WILLIAMS, Ph.D.
Rochester, Minn.

Radium as such does not have any therapeutic value. The tissue reactions which follow "radium treatment" are the result of the absorption of energy by the tissue from the radiations emitted by radium and its disintegration products.

Radium is a member of one of the three radioactive series which occur in nature. The atoms of a radioactive element eventually change into atoms of another element, and this change, or disintegration, is produced by the original atom losing mass and energy. The lost mass and energy are in one or more of three forms of radiations, called the alpha rays, beta rays and gamma rays. If all of the energy emitted by 1 Gm. of radium in equilibrium with its disintegration products should be converted into heat, it would amount to about 140 calories each hour; 92 per cent of this energy is from alpha rays, 3.2 per cent from beta rays and 4.8 per cent from gamma rays.

The alpha rays are nuclei of helium atoms which travel at a velocity which may be as high as a tenth of the velocity of light. A helium nucleus has a mass of 4 atomic units and has 2 units of positive electric charge; hence the emission of an alpha ray by an atom reduces its atomic weight 4 units and its atomic number (number of units of positive charge in the nucleus) 2 units. Although the energy of an alpha ray is quite large, it cannot travel far through solid materials; the greatest distance it can penetrate tissue is about 0.1 mm., and through materials of greater density the distance would be even less. The wall of all the ordinary containers used to hold radium or other radioactive materials is thick enough to stop all the alpha rays. Hence, when a radioactive material is enclosed in an applicator during treatment, alpha radiation cannot produce any therapeutic effect.

Beta rays are electrons which travel at a velocity which may be as high as 99 per cent of the velocity of light. An electron has a mass of approximately one two thousandth of an atomic unit of mass and has 1 unit of negative electric charge; hence the emission of a beta ray by an atom does not produce any significant change in its atomic weight, but it increases its atomic number 1 unit. The average energy of a beta ray is of the order of a tenth of the energy of alpha rays. Because of their greater velocity, smaller mass and smaller electric charge, beta rays are much more penetrating than alpha rays. Beta rays can travel through tissue a distance of approximately 10 mm. A thickness of metal sufficient to stop all the beta rays is often called a beta-ray filter, and for the commonly used metals these thicknesses are 0.5 mm. of platinum or gold, 1 mm. of silver or lead, or 2 mm. of brass, monel metal or steel.

Gamma rays are electromagnetic radiations, similar to, but of shorter wavelength than, most roentgen rays, ultraviolet light, visible radiations, radio waves and the like. Of course they, like all electromagnetic radiations, travel at the same velocity as light. The emission of a gamma ray has no effect on the atomic weight or atomic number of an atom, and gamma rays are generally emitted by the same atoms that emit beta rays. In general, the energy of the gamma rays is a little greater than that of beta rays, and they are much more penetrating than either the alpha or beta radiations. One cm. of tissue reduces the intensity of the gamma rays about 5 per cent, a half inch of lead reduces their intensity about 50 per cent, and some of these rays can be detected through 6 inches (15 cm.) or more of lead. Since most applicators containing radioactive materials are enclosed in metal of sufficient thickness to absorb all the beta rays, the therapeutic effect produced by radium treatment is due to the action of gamma radiation on the tissue.

It is not possible to predict when any particular atom of a radioactive element is going to disintegrate, but a definite percentage of the atoms present at the beginning of a period of time will disintegrate during that period. For each radioactive element the rate of disintegration is different and characteristic. Hence the period of time which elapses before half of the atoms disintegrate is called the "half-life period"; this also is characteristic of each radioactive element. The rate of disintegration of an element is not affected by chemical combination, extremes of heat, cold, pressure or vacuum, or by anything which can be done to the element. In the accompanying table is a list of that part of the uranium radioactive series which is of interest to the radiologist; in it will be found the elements in their order of disintegration, the radiations emitted, the half-life periods and other data.

Naturally Occurring Radioactive Elements Which Are Used in Radiology

Element	Atomic Number	Atomic Weight	Physical State	Radiations	Half-Life Period
Radium	88	226	Solid	Alpha	1,590 years
Radon	86	222	Gas	Alpha	3.82 days
Radium A	84	218	Solid	Alpha	3.05 minutes
Radium B	82	214	Solid	Beta and gamma	26.8 minutes
Radium C	83	214	Solid	Beta and gamma	19.7 minutes

If a preparation of pure radium (radium being used as a specific example, although any radioactive element could be used as well) is sealed in a tube, the tube immediately contains other elements; the amounts of these elements will increase for a time, and the amount of radium present will gradually decrease. However, since radium disintegrates very slowly, the amount present will remain essentially constant for many years, and hence the number of atoms of radium disintegrating in any period of time—or, which is the same thing, the number of atoms of radon formed in any period of time—will remain essentially constant for many years. The amount of radon present gradually increases until the number of atoms disintegrating in a period of time is just equal to the number of atoms being formed (number of atoms of radium disintegrating) in the same period. From then on, the amount of radon present decreases as the amount of radium present decreases; the ratio of the amounts of all those present is always the same, and radon is then said to be in equilibrium with radium. In a similar manner, equilibrium eventually will be established between all succeeding members of the radioactive series. Between radium and radium C, equilibrium is established in about two months, but it takes only about four hours for equilibrium to be established between radon and radium C. The amount of radon in equilibrium with 1 Gm. of radium is called a curie, and smaller amounts are measured in millicuries or microcuries.

Radium is commercially available only in the form of a salt, generally the sulfate, bromide or chloride, and generally a small percentage of the total weight of the preparation is the corresponding barium salt. However, the preparation is described as containing a certain weight of radium, which is the actual weight of the radium element present and not the total weight of the preparation. The actual amount of radium present is determined by comparing the amount of gamma radiation emitted by the preparation (after equilibrium has been established with radium C) with the gamma radiation emitted by a preparation whose radium content is known, or by measuring the rate at which radon is formed. Similarly, the amount of radon contained in a tube is generally measured, after equilibrium has been established with radium C, by comparing the gamma ray emission with that from a tube of radium, since the intensity of the gamma radiation from 1 mc. of radon is the same as the intensity of the gamma radiation from 1 mg. of radium, when the two are in equilibrium with radium C. Most commonly the intensity of the gamma radiation is measured with an electroscope or other suitable instrument by determining the amount of ionization produced in a given volume of air.

Since, in ordinary radium treatment, only the beta and gamma radiations are used, radium B and radium C are the only elements actually needed, because they are the source of these radiations. However, they disintegrate rapidly, and radium or radon is needed as a constant source for supplying radium B. An applicator containing radium will maintain nearly a constant amount of radium B and radium C for many years, while an applicator containing radon decreases in strength approximately a sixth every twenty-four hours, or a half every 3.82 days, and does not have any therapeutic value after about a month because all the radon and radium B and radium C have disintegrated. Since radon is the only gas in the disintegration series, it can be separated rather easily from the rest of the series, and applicators containing radon are frequently used instead of applicators containing radium; so-called "radium therapy" may be given with either type of applicator.

THERAPY

Treatment with radium can do more harm than good. To determine the best method of applying radium and the most suitable dose in each case requires training and judgment, and the best results are obtained only by physicians who have had extended experience. For these reasons, responsibility for treatment of this kind should be limited to qualified specialists.

TECHNIC

Ordinary radium therapy can conveniently be divided into three general types of application: (1) external, (2) intracavitary and (3) interstitial.

In external irradiation the radium applicator is either in contact with the skin or at some distance from the skin. Plaques containing radium, radon bulbs, tubes of radium or radon, and radium bombs are the common types of applicators used for external irradiation.

Plaque applicators usually contain from 5 to 25 mg. of radium embedded in the surface of a glazed material having an area of from 1 to 8 square centimeters. The filter in plaques is very small, seldom more than 0.1 mm. of monel metal; hence most of the beta rays may be used. Plaques are generally placed in contact with the lesion to be treated and are used for surface lesions when irradiation is to be confined to a shallow depth. Although gamma rays also are emitted, their effect on deeper tissue will be very slight during the time the beta rays produce a much greater effect on the superficial tissue.

Radon bulbs are thin walled bulbs of glass, generally less than a centimeter in diameter, containing radon. Since the filtration of the glass wall is very slight, most of the beta rays may be used. Sometimes these bulbs are used instead of radium plaques.

Tubes containing radium or radon generally have walls thick enough to absorb all the beta rays, so that only gamma rays may be used. Walls thicker than a "beta ray filter" make a mechanically stronger tube but reduce the intensity of the radiation. The "active length" (length of radioactive material) is generally about 1 to 2 cm., the overall length of the tubes from 1.5 to 3 cm., the outside diameter from 3 to 7 mm., and the wall thickness 0.5 to 2 mm. platinum equivalent (platinum or sufficient thickness of other materials to give a filtering effect equivalent to that of platinum). Often a few millimeters of rubber, bakelite, wood or similar organic filter is used between the tube and the tissue to absorb the secondary radiation from the tubes. Tubes generally contain from 5 to 100 mg. of radium, or up to several hundred millicuries of radon. Tubes are sometimes placed in contact with the skin, but more commonly they are separated a few centimeters from the skin.

Radium bombs usually contain from 1 to 10 Gm. of radium, which is enclosed in a large block of lead (or other dense metal) with an opening through which radiation can emerge. Filtration is approximately the same as for tubes, but the distance between the radium and the skin usually varies from about 10 to 40 cm.

In intracavitary irradiation the applicators are placed in a natural cavity of the body, usually in order to bring the applicator closer to the lesion to be treated. The most common applicators used are the same radium and radon tubes which are used for external application. The tubes are often enclosed in rubber or similar material to absorb some of the secondary radiation from the tubes and to increase the distance between the tube and the tissue.

In interstitial irradiation the applicators are inserted into the tissue to be treated. Radium or radon needles, containing from 1 to 10 mg. of radium or mc. of radon, with filtration of from 0.3 to 0.5 mm. of gold or platinum are often used. After the desired dose has been given, the needles are removed. Small tubes containing radon are often used, but these are never removed; they contain such an amount of radon, usually from 0.25 to 2.5 mc., that the desired dose will be delivered while all the radon disintegrates. These are commonly called permanent implants, radon seeds, gold implants or gold seeds and generally are made of pure gold having a filter of 0.3 to 0.5 mm., an outside diameter of from 0.75 to 1.15 mm. and a length of from 2 to 6 mm. They also may be made of platinum.

During recent years, in dealing with resistant tumors, the tendency has been to eliminate most or all of the beta rays by using as a filter 0.5 mm. of platinum or an equivalent thickness of some other metal. The reason for this is that beta rays have a decidedly caustic or necrotic effect at short range, that is, on the tissues immediately adjacent to the radioactive substance. This is commonly accompanied by severe pain. Elimination of beta rays by increasing the filtration prevents this necrotic effect and concomitant pain. Lead as a filter is generally employed only to treat superficial lesions.

The dose of radiation delivered to the tissue—the amount of energy absorbed by the tissue from the radiation—depends on the amount of radium or radon used, the length of time of application, the arrangement of the applicators, the filtration and the distance between the source and the tissue. The biologic effect produced by irradiation depends on the dose and many other physical and biologic factors, including the rate at which the energy is absorbed, the volume of tissue irradiated and the dosage distribution throughout that volume, the kind of tissue, the phase of the life cycle of the cells, the blood supply and many other factors.

DOSAGE

The dose is generally expressed in milligram-hours or millicurie-hours, the former being used for radium salts, the latter for radon; the two terms describe practically the same quantity. In ordinary use, however, there will be a slight discrepancy in their values if the change in value of the radon during the time of treatment is not taken into account. If the average value of radon is used, this discrepancy is practically eliminated for any normal period of treatment. To describe a treatment completely, the amount of radium or radon, the time of application, the filtration, the distance from the lesion and the type of applicator should be given. Confusion in the literature with regard to dosage is due to lack of care in recording these points; the older writers based the dose on the product of the period of application by the quantity of crystallized radium bromide ($RaBr_2 + 2H_2O$), which contains 53.6 per cent of radium element, instead of on the product of the period of application multiplied by the quantity of radium element; and this resulted in an error of about + 40 per cent. Regaud of France described the dose, when radon is used, as the quantity of radon destroyed. This he defined as the difference between the amount of radon in the applicator at the beginning and at the end of the period of irradiation. For a radium applicator this is equal to the milligram-hours multiplied by the hourly rate of decay of radon, which is 0.0075. These methods of expressing the dose are slowly being superseded by a simpler method in which the dose is stated in roentgens (the unit originally adopted for expressing roentgen dosage).

The roentgen (usually represented by r) is a measure of the amount of energy absorbed from the radiation; hence it takes into account the amount of radium or radon, time, arrangement, distance and filter (the dosage rate, at a distance of 1 cm. from a point source of 1 mg. of radium filtered by 0.5 mm. of platinum, is approximately 8.4 roentgens each hour). When the entire dose is given within a few hours, about 1,000 roentgens of gamma radiation is required to produce an erythema of the skin. Among advanced workers there is an increasing tendency to express radium dosage in roentgens, but at the present time methods of measurement have not yet been perfected and simplified sufficiently to make this a general rule.

The maximal safe dose of radiation which a person may receive day after day, called the "tolerance dose," is generally considered to be about 0.1 roentgen each day. The dose received by persons working with radioactive materials should be measured by having them carry on their person photographic film or suitable dosage measuring instruments. When the dose which they receive is near or more than the tolerance dose, added protection should be provided. It is advisable also to have frequent studies made of the blood of the personnel, for some of the earliest tissue changes produced by irradiation are indicated by changes in the blood.

BIOLOGIC CONSIDERATION

The action of radium rays on tumors depends on the kind of cells of which the tumor is chiefly composed. Each variety of cell in the body has a specific range of sensitiveness to the rays, and the sensitiveness of neoplasms corresponds closely to that of the normal cells from which the tumor is derived. The sensitiveness of cells appears to depend chiefly on their life cycle or mitotic activity. Radium rays appear to act mainly on the genetic elements (chromatin material of the nucleus) of the cells and thus may cause cellular activity to be inhibited or to be completely arrested and the cells to be injured or to disintegrate completely, the rate of effect varying with each variety of cell and with the age of the cells.

The primary biologic effect of irradiation is one of cell injury. When the degree of injury is small, the tissue eventually may be able to recover from it. Hence, in general, it is undesirable to irradiate normal tissue, and precautions should be taken to irradiate as little normal tissue as possible while treating a lesion. Precautions must be taken to protect the personnel working with radioactive materials from receiving enough radiation to produce permanent tissue damage in their own bodies.

As already mentioned, the action of radium rays on pathologic lesions depends on the sensitiveness of the particular varieties of cells affected. This applies to benign, inflammatory and malignant processes. The leukocytes, especially the lymphocytes, and polymorphonuclear and eosinophilic leukocytes, are the most sensitive of all human cells. Next in sensitiveness come the mucus producing cells in the basal epithelium lining the acini of the salivary glands, pulmonary bronchi, stomach and intestine. The basal epithelial cells (spermatogonia) of the testis and ovary come third in the order of sensitiveness and account for the susceptibility to irradiation of the respective genital glands. Young connective tissue cells are comparatively sensitive, and mature connective tissue cells are comparatively insensitive to irradiation. Less and less sensitive, or more and more resistant, to the direct action of the rays are cartilage cells, muscle cells, bone cells, fat cells and finally nerve cells. In the eye the two most sensitive structures are the conjunctiva and the epithelium of the crystalline lens. Doses of radiation insufficient to cause an inflammatory reaction of the eyelids are not likely to cause the conjunctiva or the lens to react. Doses sufficient to produce conjunctivitis may lead to the formation of cataract months or years later, especially in children. As far as tumors are concerned, those composed chiefly of lymphocytes are extremely sensitive and retrogress rapidly after exposure to the rays. Tumors derived from the spermatogonial cells of the testis (seminoma or embryonal carcinoma) also are sensitive, though less sensitive than growths incidental to Hodgkin's disease, lymphosarcoma or lymphatic leukemia. Among bone tumors, diffuse endothelioma (Ewing) is quite sensitive, chondrosarcoma moderately sensitive and osteogenic sarcoma quite resistant to irradiation.

INTRAVENOUS AND ORAL ADMINISTRATION

When taken internally over a certain period of time, solutions of radium may have a deleterious effect on the blood corpuscles. Under these circumstances the radioactive element is eliminated chiefly through the bowel and kidneys, but a small proportion is disseminated through the body and finally lodges in bones, the radioactivity of which may therefore increase considerably. In time these radioactive deposits may lead to bone sarcoma; therefore solutions of radium, when used to treat internal diseases, should be used with caution and only for a limited time.

When solutions containing radon are taken internally, the emanation is rapidly lost from the body, a large proportion escaping during the process of drinking and the remainder being eliminated through the bowel.

Solutions of radium chloride, and radon (radium emanation) contained in drinking water, constitute the chief methods of oral administration; intravenously, radium chloride solution is generally used. The evidence available on the effect of solutions containing radium or radon (radium emanation) in the treatment of disease is in general not well controlled and such solutions, therefore, are of doubtful value. Certainly there is no basis for the use of radium or radon (radium emanation) in conditions such as anemia, habitual constipation, glycosuria, sexual impotence, glandular inefficiency or for purposes of rejuvenation in general. It is noteworthy that many of the conditions in which radon is recommended are chronic conditions in which any new method of treatment may seem temporarily beneficial.

The daily administration of radon (radium emanation) has been reported to give beneficial results in various conditions, including infections, acute articular rheumatism, endocarditis, chronic arthritis, neuritis, hypertension, thromboangiitis obliterans and arthritis deformans. Many of the so-called emanators and activators on the market impart such small amounts of radon (radium emanation) to the water which contains them that their effect, if any, is probably psychic. Commercial exploiters of mineral springs have made much of the radioactive content of the water and have attributed therapeutic benefit to this factor. In most cases the radioactivity of spring water is very small and probably has nothing to do with the therapeutic effects noted.

Solutions of radium chloride are given in doses of from 10 to 50 micrograms. Radioactive substances introduced intravenously are eliminated largely through the bowel and kidneys, and excessive doses may produce degeneration of renal cells and hyperemia and hemorrhage of the mucosa of the colon.

From an examination of the available evidence it would appear that the value of the internal use of radium solutions or of water containing radon, in chronic arthritis, gout, neuritis and high blood pressure, has not been demonstrated by controlled clinical evidence; in spite of many years of trial, acceptable evidence has not become available, and until better evidence becomes available the Council on Physical Medicine has decided not to accept generators for the production of water charged with radon or radium solutions intended for intravenous use.

RESULTS OF TREATMENT IN PATHOLOGIC CONDITIONS

Radium treatment is often effective in myelogenous and lymphatic leukemia. In the former, topical application of radium over the region corresponding to the enlarged spleen usually causes the organ to diminish in size rapidly, and the leukocytes undergo a corresponding reduction in number. In some cases, irradiation of the spleen alone is not sufficient and the long bones also must be treated. Irradiation of the long bones or of the lymph nodes in lymphatic leukemia is best carried out with roentgen rays rather than radium. In many cases a substantial improvement in the general condition accompanies the reduction in size of the spleen and superficial nodes and the fall in the leukocyte count. Acute leukemia does not respond well to irradiation, but in the more chronic forms irradiation usually leads to prolonged remission of symptoms, although treatment may have to be repeated at varying intervals from time to time. When the spleen has been irradiated many times, it tends to become fibrous and radium gradually loses its effect. In cases of severe anemia, exposure to radium should be repeated with caution; otherwise there may be danger of increasing the anemia. Radium is applied for varying lengths of time over the spleen and superficial lymphatic enlargements only or in conjunction with irradiation of the long bones. Usually a total exposure of successive areas for twenty-four hours at one time is sufficient. This may be repeated at intervals of one week or longer, depending on the exact dose given. During the past few years, phosphorus, when made artificially radioactive by a cyclotron and when given intravenously, has been found to yield results which are superior to those obtained by radium applied to the surface of the body.

In menorrhagia and metrorrhagia, which are often concomitants of fibroid disease of the uterus, radium therapy is frequently of real value. It is accomplished best by intrauterine application, although sometimes the radium may be placed in the posterior vaginal fornix and supplemented with distance screening over the fundus. In young women the dose should be controlled so that a premature menopause does not occur. A universal tube applicator containing 25 to 50 mg. of radium in the form of radium sulfate, filtered through 0.5 mm. of silver and 2 mm. of gum rubber, and placed in the uterine cavity for fourteen hours, will bring on amenorrhea in most cases. If necessary, the treatment may be repeated after an interval of six months. In young women, in whom permanent amenorrhea is to be avoided, a fourth to a half of this dose is often sufficient.

Lymphadenoma, lymphosarcoma and mediastinal and abdominal growths of a sarcomatous nature are often reduced in size by the application of radium, with concomitant improvement in the general condition.

The sensitiveness of malignant tumors of bone varies according to the susceptibility of the essential cells of the tumor. Thus diffuse endothelioma, otherwise known as endothelial myeloma, is quite sensitive, and the rate of regression of this tumor corresponds to that of the chronic form of lymphosarcoma and Hodgkin's disease. Chondrosarcoma is rather resistant, its rate of regression depending on the proportion of young cartilage cells in the tumor. True osteogenic sarcoma is comparatively resistant to irradiation. Some of these tumors may undergo a measure of regression after exposure to radium, but the regression is seldom pronounced and practically never complete.

Carcinoma involving certain organs responds well to the application of radium. In carcinoma (not adenocarcinoma) of the uterine cervix, the results obtained by expert workers are at least equal to those which follow surgical intervention. Carcinoma of the thyroid gland also is comparatively sensitive. On the contrary, adenocarcinoma, wherever situated, tends to resist irradiation. Carcinoma of the gastrointestinal tract is seldom greatly influenced by radium treatment.

Radium treatment is of considerable value in bringing on shrinking and fibrosis in tuberculous adenitis.

Improvement has been noted in certain skin diseases when treated with radium rays; for example, lichenified eczema, epithelioma and keratosis, psoriasis, xanthoma, localized mycosis fungoides and fibroma.

Lupus vulgaris, when all other treatment has failed, is sometimes favorably influenced by radium.

In cavernous nevus the course of the disease is favorably influenced. The treatment is lengthy and tedious. Overexposure should be avoided, especially about the face, for it brings about scarring. Much care and experience are needed in order to obtain good results.

The removal of warts and papillomas and the treatment of pyogenic granulomas by radium are generally successful. If the exposure is timed properly, involution occurs in from three to four weeks.

Good results have also been reported in the treatment of conditions which often follow injuries, such as keloids, painful scars and fibrous adhesions.

Moles, especially of the pigmented variety, should not be irradiated. They can be destroyed by means of high frequency current or they can be excised surgically.

For many years certain concerns which deal in radium and its emanation products have made it possible for any physician to rent radium or radon and to use it in the treatment of some of their cases. This service was probably provided to meet a considerable demand on the part of physicians who did not realize that the use of these radioactive agents by physicians who have not had special training and experience is fraught with considerable danger, and the results of treatment under these conditions are not likely to be as good as they should be. For this reason the attitude of the Council on Physical Medicine has been and still is that the rental of radium or radon to physicians who have not had special training and experience should be discouraged.

Mental Changes.—Coma is a state of complete unresponsiveness to the environment. The patient's reactions are limited to elemental reflexes, and even some of these are impaired. Semicoma is a condition in which there is responsiveness to some of the elemental mental functions, such as calls by name, reacting to noise and reacting to a visual threat. There is no significant defect in the elemental reflexes. Stupor is a condition of greater awareness where the patient has no defect in elemental reflexes, responds to elemental mental functions and, in addition, reacts to verbal commands, having an ability to execute simple things, such as shutting the eyes and sticking out the tongue. Confusion is a state in which there is only a mild disturbance in the state of consciousness. The elemental reflexes, elemental mental functions and reactions to simple commands are usually intact. These patients present chiefly orientation difficulties.—Wortis, S. Barnard; Herman, Morris, and London, Jack: Mental Changes in Patients with Subdural Hematomas, in Trauma of the Central Nervous System, Baltimore, Williams & Wilkins Company, 1945.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

CONTRACEPTIVE JELLIES AND CREAMS (See New and Nonofficial Remedies, 1945, p. 355).

The following articles have been accepted:

DUREX PRODUCTS, INC., NEW YORK

Lactikol Creme: A water dispersible nonfatty stearic acid and glyceryl monostearate cream, having a p_H of 4.9, prepared from the formula:

	Per Cent
Stearic acid	15.00
Glyceryl monostearate	7.50
Glycerin	8.00
Glyceryl monoricinoleate	1.50
Sodium lauryl sulfate	0.50
Lactic acid	0.50
Perfume	0 07
Water sufficient to make	100.00

Actions and Uses.—(See article Contraceptive Jellies and Creams.)

Dosage.—5 cc.

Lactikol Jelly: A water soluble jelly formed from tragacanth, karaya and acacia, having a p_H of 4.15, prepared from the formula:

	Per Cent
Tragacanth	2.70
Karaya	1.00
Acacia	1.00
Lactic acid	1.50
Glycerin	16.00
Glyceryl monoricinoleate	1.00
Sodium lauryl sulfate	0.20
Butyl ester of parahydroxy benzoic acid	0.02
Oxyquinolin sulfate	0.05
Perfume	0.04
Water sufficient to make	100.00

Actions and Uses.—(See article Contraceptive Jellies and Creams.)

Dosage.—5 cc.

SYRINGE APPLICATORS FOR CONTRACEPTIVE JELLIES AND CREAMS (See New and Nonofficial Remedies, 1945, p. 357).

The following articles have been accepted:

DUREX PRODUCTS, INC., NEW YORK

Lactikol Plunger Applicator: A transparent plastic tube threaded at the blunt intravaginal end to screw onto the tubes of Lactikol Creme and Jelly to permit filling by compression of the tube. The full capacity is 5 cc., the recommended dose.

Lactikol Metri-Dose Applicator: A transparent glass tube graduated to permit delivery of from 5 to 8 cc., slightly constricted at the intravaginal end to permit filling, and fitted at the distal end with a rubber compression bulb with central wire spring device to permit adjustment of the volume of jelly or cream to be delivered.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1945, p. 610).

The following additional dosage form has been accepted:

SCHIEFFELIN & CO., NEW YORK

Tablets Thiamine Hydrochloride: 3 mg.

ASCORBIC ACID (See New and Nonofficial Remedies, 1945, p. 622).

The following additional dosage form has been accepted:

SCHIEFFELIN & CO., NEW YORK

Tablets Ascorbic Acid: 100 mg.

HEXESTROL (See New and Nonofficial Remedies, 1945, p. 435).

The following dosage form has been accepted:

ORTHO PRODUCTS, INC., LINDEN, N. J.

Tablets Hexestrol: 1 mg. and 3 mg.

SATURDAY, JANUARY 26, 1946

VACCINATION FOR INFLUENZA

Recently Salk and his colleagues[1] reported the efficacy of vaccination against influenza, using a preparation which contained larger quantities of virus than usually employed, with the purpose of producing a higher degree of immunity. More than 2,000 persons at the Ypsilanti State Hospital in Michigan were studied. At the Eloise Hospital Infirmary 5,737 persons were involved. At the Ypsilanti State Hospital alternate persons in certain wards who were selected for study received a subcutaneous injection of 1 cc. of the virus vaccine or a similar inoculation of control material. One thousand and thirty-five were given the vaccine and 1,051 received the control inoculation. This took place on Dec. 21 and 22, 1942. Between Jan. 5 and 12, 1943 2,879 received the vaccine and 2,858 received control material at the Eloise Hospital and Infirmary. Blood for serologic study was obtained from approximately 10 per cent of the vaccinated group at the time of vaccination and again two weeks later. The vaccination raised the antibody titers of the majority beyond the range of the group prior to vaccination. Thus, prior to inoculation the type A antibody titers higher than 256 were found in only 6 per cent of patients, whereas 71 per cent had titers of this level or more after vaccination. Similarly, type B antibody titers of 256 or higher were found in only 10 per cent before inoculation but in 78 per cent postvaccinally.

A special effort was made to determine the duration of increased antibody titer. Bleedings were carried out at intervals of two weeks, four months and one year. For the type A virus the results could be summarized as follows: Antibody titers of 256 or more were found in 15 per cent of the group before vaccination, in 83 per cent two weeks later, in 69 per cent four months later and in 66 per cent at the end of a year. For the type B virus similar levels of antibody titers were found in 6 per cent before vaccination and in 82 per cent, 70 per cent and 57 per cent at the corresponding intervals after vaccination.

Nearly a year after vaccination an epidemic of influenza A occurred in the general population adjacent to the Ypsilanti State Hospital. Several of the ward attendants acquired influenza about two weeks before the disease became manifest among the inmates. When the vaccination study was begun not all wards had been included, and in those in which vaccinations were done only one half received the virus vaccine, the remainder having been inoculated with control material. In the intervening year the changes in composition in the wards were comparatively slight. Consequently a program of case finding was instituted. Influenza was frequent in some of the wards; in these wards the population was essentially unvaccinated. In the group of "vaccinated" wards, about 40 per cent of the residents of which had been vaccinated, the incidence of influenza seemed to be definitely limited either because cases did not occur or because those which did appeared sporadically.

The investigators presented evidence also that the vaccine used remained stable for more than a year when stored in a refrigerator. This was shown by mouse protection tests and the capacity to induce a rise in antibody level in human beings similar to that obtained by fresh vaccine.

The laboratory evidence of prolonged antibody rise following influenza vaccination, the appearance of an epidemic of influenza about a year after inoculation and the epidemiologic pattern taken by the disease strongly suggest that vaccination as long as a year old may prevent or at least limit outbreaks which might have been severe in certain segregated institutional groups. Further progress in the preparation of potent and long lasting vaccines and in technics of administration are doubtless impending.

NUTRITIONAL ANEMIAS IN CHILDREN

The significance of nutritional factors in the etiology of the anemias of children has been reemphasized in recent investigations. The importance of dietary protein,[1] of the B vitamins[1] (possibly folic acid in particular) and of iron[2] has been stressed in current studies. In one severely anemic infant with an allergy to cow's milk, for example, the administration of food containing "protein" in the form of amino acids[1] was followed by a prompt recovery. Subsequent studies will probably confirm the therapeutic need and value of additional dietary protein in some chronic cases of anemia in children.

Investigations of the identity of the B vitamin or B vitamins involved in the nutritional anemias of infancy have not proceeded far enough to permit conclusions. However, the administration of liver preparations[1] produced a dramatic recovery from the anemia in one child thus treated. This factor may be folic acid and thus identical with that which apparently benefits certain types of macrocytic anemias in the adult.[3] Further studies of this important practical problem will be awaited with interest.

[2] Abbott, O. D., and Ahmann, C. F.: Iron Deficiency Anemia in Children, Am. J. Dis. Child. 58:811 (Oct.) 1939.

As is well known, a lack of iron may also be involved in the etiology of the nutritional anemias of children. This problem seems to be somewhat more acute in certain areas of the country where "endemic anemia" from iron deficiency has been described.[2] This observation has been confirmed in more recent studies of hemoglobin values in rural school children in Florida.[4] Of a total of 2,205 children from 6 to 18 years of age examined, 42.3 per cent were distinctly anemic, having hemoglobin values ranging from 3.6 to 11.4 Gm. per hundred cubic centimeters, 35.8 per cent were subnormal (11.4 to 13.6 Gm. per hundred cubic centimeters) and only 21.9 per cent were considered normal (above 13.5 Gm. per hundred cubic centimeters). A lack of dietary iron was shown to be the primary deficiency in these cases, since rapid hemoglobin regenerations followed the administration of iron salts.

These observations again emphasize the importance of proper nutrition, especially with respect to protein, the B vitamins and iron, in maintaining normal hemoglobin formation in the growing child.

HAZARD OF ANOXIA IN NITROUS OXIDE ANESTHESIA

Anesthesia by inhalation of nitrous oxide gas presents a number of advantages such as the prompt and pleasant induction of sleep and the rapid elimination from the body. The gas has not been found to have a toxic effect on any tissue. The single serious imperfection of nitrous oxide is its lack of potency. When given with a concentration of oxygen found in air, nitrous oxide will not produce a degree of narcosis in many persons that meets the requirements of surgical anesthesia. To overcome this difficulty McKesson in 1911 introduced the principle of fractional rebreathing into gas anesthesia and a new technic in which induction of anesthesia was accomplished with undiluted nitrous oxide and the saturation technic. When saturation is practiced, 100 per cent nitrous oxide is continued to the point of profound asphyxia and respiratory arrest. At this point, if the pulse becomes irregular or slow, oxygen is given under pressure sufficient to inflate the lungs. After the single inflation of lungs with oxygen, an anesthetic mixture is provided to maintain narcosis and the necessary degree of muscle relaxation. If in the course of the operation this mixture proves inadequate to maintain relaxation, the asphyxial procedure is repeated as a secondary saturation.

McQuiston and his co-workers[1] maintain that a mixture of 20 per cent oxygen and 80 per cent nitrous oxide may be used without causing serious anoxemia. In their analyses of blood gases in patients who received nitrous oxide anesthesia they found that any appreciable reduction in oxygen below 20 per cent may become extremely dangerous to the patient. In all their experiments, when the proportion of oxygen in the inspired gases was below 13.7 per cent, the arterial oxygen tensions were in the range of extreme asphyxia, 30 mm. of mercury. These experiments make it obvious that the administration of nitrous oxide is often accompanied by anoxemia and that the degree of anesthesia is more dependent on the reduction of oxygen than on an increase of concentration of nitrous oxide.

The important contribution of Courville,[2] based on a study of 13 cases 9 of which terminated fatally, demonstrates most emphatically that nitrous oxide-oxygen anesthesia may cause serious and even fatal results. A patient may die during the anesthesia with absence of any pathologic lesions at necropsy sufficient to account for death. The cause of death in this type of case has been ascribed to status thymicolymphaticus, idiosyncrasy or anoxemic depression of the respiratory center. In a second group described by him, the patient may survive for hours or months and then succumb. Cases corresponding to this classification are numerous, and most anesthetists with wide experience are familiar with one or more in their own or in the practices of others. Immediate nervous manifestations usually consist of generalized convulsive seizures, muscular rigidity and persistent coma, at times terminating fatally with signs of "decerebrate rigidity." Delayed symptoms may occur in the form of a psychosis, the parkinsonian symptom complex or disturbance of special sensation, particularly in the form of a partial or complete amaurosis. The patient may recover entirely after an anoxemic episode, may survive for a variable period with residual symptoms or may die within a few days. Similar cases were reported by Lowenberg, Waggoner and Zbinder, O'Brien and Steegman, Stewart and others. The only conclusion to be drawn from the cases reviewed is that the consequences of nitrous oxide anesthesia are due to the accompanying anoxia. Certain contributory conditions have been recognized in the production of anoxemia, such as pulmonary lesions, diminished cardiac reserve and hyperthermia.

Barach and Rovenstine[3] stress that, except in the presence of these specific conditions, methods are not available for distinguishing between persons who may suffer severely from brief bouts of anoxia and those who will recover fully after prolonged oxygen want. They believe that the mortality and morbidity from nitrous oxide-oxygen anesthesia as practiced in offices is much greater than is generally known. Protection of the public against death or permanent impairment of mental functioning from anoxia demands widespread dissemination of the fact that asphyxia of even very short duration must be regarded as a grave hazard to the great majority of persons. They propose that nitrous oxide-oxygen anesthesia should not be administered with an oxygen percentage of less than 20. Should anesthesia with a 20 per cent oxygen-80 per cent nitrous oxide mixture prove not sufficiently deep, other technics should be used rather than resort to asphyxia or even so-called moderate anoxia. Cylinders containing 80 per cent nitrous oxide and 20 per cent oxygen will provide an unvarying concentration of these gases with a cylinder pressure of 700 pounds. They feel that the increased cost of such mixtures should not be made the basis of permitting a practice that is dangerous as well as unphysiologic.

Current Comment

HOSPITAL RESIDENCIES UNDER THE G. I. BILL

For some time a subcommittee of the Committee on Postwar Medical Service has been seeking a clarification of the educational provisions of the G. I. Bill of Rights as they might apply to hospital residencies, which are being sought by physician veterans in great numbers. Elsewhere in this issue is an explanation of the manner in which this law will operate in the case of residencies, whether or not the hospital is affiliated with a medical school. Important questions raised repeatedly have been: Is a hospital offering an acceptable residency program eligible to participate? Are physician veterans eligible for subsistence benefits while pursuing such a course of study? May a veteran commence his residency training while on terminal leave? These questions are now answered in the affirmative, with certain qualifications fully described in this statement, which was approved by the Central Office of the Veterans Administration. It can serve as a useful guide to hospitals and physician veterans alike, since all necessary procedures are described in detail. The modified provisions of the new law, passed in December 1945, are included. Certain of these were advocated to Congress by the Committee on Postwar Medical Service and its subcommittee. It is now not necessary for a physician veteran of any age to prove that his education was interrupted to become eligible; more satisfactory arrangements for tuition payments for short courses are provided; tuition and subsistence benefits will not be charged against the veteran's bonus, should one be voted later by Congress; and the subsistence benefits are increased.

PRESCRIPTION WRITING

The best medical treatment is that fitted to the individual patient. Drug therapy, highly significant in most medical treatment, is secured by the prescription. As Sollmann aptly says, a prescription is "an order for medicine sent by a physician to a pharmacist." Some of the practical requirements for writing an effective and correct prescription are often neglected. The instructions for the pharmacist and patient must be legible and intelligible; this is why English is now preferred to Latin. The prescriber should use correct, descriptive names for the ingredients and not just their trade names; such description insures fewer misunderstandings. If an ingredient is official or otherwise open to manufacture by several firms, a firm name should be placed adjacent to the ingredient if the physician wishes to show his confidence in any one manufacturer; otherwise any brand may be used to fill the prescription. The use of English abbreviations and numbers as designations for drugs should be avoided. Complex mixtures should not be ordered if simple ones will suffice. Unrelated substances such as purgatives and hypnotics are not properly included in a single prescription. They are best prescribed separately and timed in their administration to be most effective. The physician should be mindful of the frequency with which prescriptions are refilled without his knowledge. Thus he may limit the number of doses to the actual needs of the patient and state specifically on the prescription whether it can be refilled and, if so, how often. The importance of such directions, for example when barbituric acid compounds are prescribed, is obvious. Of course the pharmacist bears the responsibility of filling the prescription; when he is in doubt concerning the ingredients or directions, it is his moral responsibility to call the prescribing physician; to do otherwise invites disastrous results.

ADVANCES IN MALARIAL RESEARCH

A report in the January 4 issue of *Science* of the Board for the Coordination of Malarial Studies[1] lists a number of significant advances in the study of malaria. Studies on immunity in the avian infections have given information on the cross immunization which obtains with different species of parasites. The studies on immune response of human subjects to malarial antigen have been disappointing either in the prevention or modification of the disease or in the production of complement fixing antibodies which might be useful in differentiating between a latent infection and a cure in vivax malaria. A great number of chemical compounds have been investigated for antimalarial activity in various avian infections and in human malaria. Among the practical advances resulting from these studies may be mentioned: 1. The development of better methods for the use of quinacrine (atabrine) in the suppression and treatment of malaria, which led to the demonstration that this compound is superior to quinine. 2. Development of compounds superior to quinacrine. Among these are several members of the 4-aminoquinoline series. In this group SN7618, 7-chloro-4-(4-diethylamino-1-methylbutylamino) quinoline, has received the most extensive study, both in civilian and in military establishments. This compound is an effective suppressive when administered no more frequently than once a week in a well tolerated dose. It will also cause an abrupt termination of the clinical attack of vivax malaria and will cure falciparum malaria when administered for only one or two days. It does not discolor the skin, as does quinacrine, nor does it give the disagreeable gastrointestinal symptoms which are sometimes seen with the administration of quinacrine. 3. The exploration of the 8-aminoquinolines. The field of investigation of suppressive drugs has been extended, the major emphasis being focused on the study of the 8-aminoquinolines with the hope of discovering a nontoxic curative agent. This line of investigation received impetus from published reports of British investigation of pamaquin (plasmochin) in vivax malaria. Curative action of pamaquin was demonstrated in vivax malaria due to both domestic and Southwest Pacific strains of P. vixax.

VITAMIN CONTENT OF HUMAN MILK

Since milk is the basic food of the infant and many babies are raised on formulas containing cow's milk adjusted to resemble human milk, a knowledge of the complete chemical composition of both types of milk is desirable. The content of all the grosser constituents such as fat, carbohydrate, protein and minerals is well known. Recently Macy and her associates[1] have added to our knowledge of the vitamin content of human milk. In this series of studies the newer microbiologic and chemical procedures were used to determine the concentrations of vitamin A, ascorbic acid, nicotinic acid, biotin, pantothenic acid, thiamine and riboflavin in twenty-four hour samples of human milk. This period of collection was adopted to remove the possibility of diurnal variations. For this study a number of pregnant and lactating women were either given special diets of high vitamin content or allowed to choose their own diets. It was found that the vitamin content of the milk from those women who choose their own diet was lower than those on the planned diets, although the differences were small. Using the values for the vitamin content of human milk which were obtained by the Detroit group, Maynard and his co-workers[2] made comparisons with the vitamin content of cow's milk. Human milk was found to be higher than bovine milk in regard to ascorbic acid, nicotinic acid and inositol. Cow's milk was found to contain more thiamine, riboflavin, pyridoxine, biotin and pantothenic acid than human milk. A factor to be taken into consideration when comparing these values is that the normal commercial processing and delivery of cow's milk may cause considerable loss of the riboflavin and ascorbic acid activity.

PULMONARY INSTILLATION OF PENICILLIN IODIZED OIL

Bryson,[1] Barach[2] and others have shown that penicillin aerosol penetrates the lungs and that respiratory penicillin may be recovered from the urine. The aerosol method of pulmonary therapy, however, necessitates four or five inhalations daily to maintain effective quantities of penicillin in the lungs. Radiographic control of the location of the therapy is impossible. Romansky and his associates[3] of the Walter Reed General Hospital therefore tested the feasibility of pulmonary instillations of penicillin in iodized oil. Calcium penicillin was thoroughly blended with 40 per cent iodized oil, the resulting mixture containing 1,500 Oxford units per cubic centimeter. Stability tests showed that penicillin remains suspended in the mixture and does not settle out or deteriorate even after sixty days storage at room, incubator or refrigerator temperature. Under radiographic control from 1 to 3 cc. of this mixture was injected through the trachea into the bronchi of 8 rabbits. Blood levels varying from 0.039 to 1.25 Oxford units per cubic centimeter were found during the next two hours, the titer depending on the amount of the penicillin injected. Gross and microscopic studies of the lungs and other organs two months later showed no abnormalities that could be attributed to this form of therapy. Ten patients with severe saccular bronchiectasis and 2 with pulmonary abscess were selected for clinical trial. The lesions in all 12 cases were confined to a single lobe. After preliminary cocainization of the posterior pharynx, from 7 to 10 cc. of penicillin iodized oil was introduced into the diseased lobe of each patient, fluoroscopic visualization furnishing an accurate check of the localization of the injected material. Immediate or subsequent discomfort due to the mixture was not observed. In most cases, assayable levels of penicillin were found in the blood during the first three hours after the instillation. In all patients, penicillin continued to be excreted in the urine for at least twenty-four hours. In certain cases a gradual reduction in the amount of sputum to approximately 50 per cent of the original amount occurred by the seventh day. Romansky believes that the chances of curing far advanced bronchiectasis, lung abscesses or any other type of chronic pulmonary suppuration by this method are remote. He is convinced, however, that there is a distinct possibility that the bacterial flora of diseased lungs may be altered by such local therapy so as to make subsequent surgical intervention safer. Further studies of therapeutic possibilities are in progress.

MEDICINE AND THE WAR

HOSPITAL RESIDENCIES UNDER THE G. I. BILL

This statement by a subcommittee on veterans' affairs of the Committee on Postwar Medical Service was compiled for the information of approved residency hospitals and physician veterans by that subcommittee, the Council on Medical Education and Hospitals and the Bureau of Legal Medicine and Legislation of the American Medical Association. The provisions of the amended Servicemen's Readjustment Act are included. The statement has been approved for publication by the Central Office of the Veterans Administration.

1. *Eligibility of Hospitals.*—On Nov. 9, 1945 the chairman of the subcommittee on veterans' affairs of the Committee on Postwar Medical Service of the American Medical Association submitted for the consideration of the Administrator of Veterans' Affairs the question as to whether payment of tuition can be made to hospitals which furnish physician veterans advanced hospital education beyond internship. In the letter it was stated that the instruction to be furnished to the physician veterans should be regarded as an educational program, as distinguished from "on the job training," for the reason that it involves organized teaching on rounds and in conferences as well as classroom conferences dealing with autopsy findings, medical problems in the hospital, x-ray diagnosis, laboratory studies and other organized educational features which definitely stamp this training as education. It was also stated that such a program of instruction entails expenditures by the hospitals which would be unnecessary if patient care alone were involved and that the services of additional physician teachers would be required in order to provide the necessary instruction.

In reply to this letter from the chairman of the subcommittee of the Committee on Postwar Medical Service, the Administrator of Veterans' Affairs ruled that ". . . the training contemplated in connection with residencies and fellowships is not 'training on the job' . . . but is in the nature of institutional training." This applies to all acceptable residency hospitals, whether or not they are affiliated with a medical school. The ruling means that otherwise qualified physician veterans pursuing the contemplated training in connection with residencies or fellowships are eligible for subsistence benefits and that approved hospitals are eligible to apply for tuition remuneration. (See section 6).

2. *State Approval of Hospitals.*—Although the Veterans Administrator has established the general principle that hospitals conducting acceptable residencies are eligible for participation under the bill, it is still necessary for each residency hospital to seek approval as an individual institution from the appropriate state agency. The law requires the governor of each state to designate an authority in each state to approve educational institutions. In most states this agency is the Office of Education, by whatever name it may be called. A revised list of these agencies for all the states is given in section 10. No hospital can participate unless it is approved by the state agency; veterans receive no subsistence allowance while serving as residents in a hospital not so approved.

It is the responsibility of these state agencies to see that only institutions offering education of a high quality be certified for participation, as a protection to the veteran.

3. *Eligibility of Veterans.*—Honorably discharged physician veterans of this war are eligible for educational benefits for a period of time equal to one year plus the duration of their active duty since Sept. 16, 1940, and prior to the termination of the war, not including time spent on active duty in the A. S. T. or Navy V-12 programs, and not to exceed a total period of four years. It is no longer necessary for the veteran to demonstrate that his training was interrupted by the war, regardless of his age when entering active duty. The period of training must be commenced within four years of discharge, or the termination of the war, whichever is later, and completed within the nine year limitation. In no case may the period of education exceed four years.

4. *Establishment of Eligibility.*—It is necessary for the veteran to establish his eligibility formally. This he does by filing an application on Veterans Administration Rehabilitation form 1950 at the regional office (see section 11) of the Veterans Administration. A certified copy of his discharge or a photostatic copy of his discharge should accompany the application. From the regional office the veteran receives a Certificate of Eligibility and Entitlement (Veterans Administration form 1953), which indicates the duration of the training to which he is entitled. This certificate must be endorsed by the approved hospital and forwarded to the regional office of the Veterans Administration. Benefits cannot be paid unless and until this process is complete. It is important for the veteran to make certain that the hospital has been approved by the appropriate state agency (see sections 2 and 10). It is also to the veteran's interest to make certain whether the hospital is also approved by appropriate nongovernmental approving agencies, lest the work done proves later to be useless for such special purposes as certification by one of the American Boards in the medical specialties.

5. *Subsistence Allowance.*—The veteran then receives a monthly subsistence check for $65 if without dependents or $90 per month if he has a dependent or dependents. These payments will not be made during terminal leave. Public Law 268, approved Dec. 28, 1945, repeals section 1505 Public Law 346 reading in part as follows: "In the event there shall hereafter be authorized any allowance in the nature of adjusted compensation, any benefits received by, or paid for, any veteran under this act shall be charged against and deducted from such adjusted compensation."

6. *Payments to Hospitals.*—The law and Veterans Administration regulations make special provisions for payments to educational institutions having no established tuition fee. These apply to approved residency hospitals, which rarely if ever have an established tuition fee; in fact, some participating hospitals will provide a modest stipend to the veteran and may even provide facilities for living in the hospital as part of his training, in which case the other provisions of this statement still apply. Regarding payments to hospitals, there are four alternatives available to hospitals:

a. The hospital may request no payments; this does not affect subsistence payments to veterans.

b. The hospital may have a regularly established tuition fee, which it may request from the regional office of the Veterans Administration for its resident veterans; this would usually be limited to some university or medical school hospitals offering fellowship or graduate work including residency training.

c. Hospitals may avail themselves of the regulations in Veterans Administration instruction No. 6, Title II, Public Law 346, amplified in conferences with the Veterans Administration. Any approved educational institution that has no established tuition fee or whose established tuition is considered inadequate compensation may charge for each veteran enrolled in a full time course as much as $15 per month, $45 per quarter or $60 per semester. In residency hospitals the length of the course of instruction is fifty-two weeks (including vacation), which does not fall within the Veterans Administration definition of an ordinary school year, as a period of thirty to thirty-eight weeks. Residency hospitals selecting this basis of compensation would be paid $15 per month, or $180 for a course of fifty-two weeks.

This alternative will probably apply to most hospitals desiring tuition remuneration.

d. A hospital that has no established tuition or that considers its established tuition charges to be inadequate compensation and desires payments in excess of that described in section 6 (c) may, in accordance with the provisions of Veterans Administration instruction No. 6, be paid fair and reasonable compensation not exceeding the estimated cost of teaching personnel and supplies for instruction. Hospitals desiring compensation on this basis will be required to submit through the manager of the regional office to the Assistant Administrator for Vocational Rehabilitation and Education, Veterans Administration, Washington, D. C., information on cost of teaching personnel and supplies for the courses of instruction. Information will also be required as to the value of services rendered by the residents and fellows to the institution. The value of such services must be offset under this basis of compensation against any costs for teaching personnel and supplies incurred in giving the courses in question. Medical school hospitals especially may wish to follow this alternative for fellowships involving residency training, when there is no established tuition fee for such work.

Note that it is only in connection with section 6 (d) that it is necessary for the hospital finally to deal directly with the Central Office of the Veterans Administration in Washington. In all other negotiations described in this statement the hospital as well as the veteran deal with local authorities: the regional office of the Veterans Administration or, initially, with the state agency which approves educational institutions.

7. *Responsibility of Hospitals.*—It is the responsibility of every participating hospital to maintain an educational program of high quality, fulfilling established and generally accepted standards for such work. No hospital is justified in embarking on or continuing residency programs unless these are acceptable not only under the law but professionally as well.

8. *Terminal Leave Period.*—An eligible physician veteran may embark on any educational program within the provisions of the act during his period of terminal leave. During this period of time tuition payments can be made to the approved educational institution to the same extent that they may be made after the medical officer's discharge. However, subsistence payments will not be paid to the veteran during the terminal leave period.

9. *Short Intensive Postgraduate or Training Courses of Less than Thirty Weeks.*—Institutions providing review and refresher courses of less than thirty weeks, having regularly established fees, must be approved by the appropriate state agency (see section 10) and must arrange for tuition payments with the regional offices of the Veterans Administration (see section 11). The veteran must establish his eligibility for this work as described in section 4. The fee can be charged, provided the cost is not in excess of the rate of $500 for a full time course for an ordinary school year. If the customary charges are in excess of the rate of $500 for an ordinary school year the Veterans Administration must find that the agreed cost of such courses is reasonable and fair. However, for review and refresher courses there will be charged against the veteran's time period of eligibility the proportion of an ordinary school year which the cost of the course bears to $500. For example, if an eligible veteran elects a two month course for which $250 is paid, there will be charged against the veteran's period of eligibility for training, not two months, but a half of an ordinary school year, since $250 is half of $500.

By taking such a review or refresher course the veteran does not forfeit the right for further education, within the limits of the period of eligibility for instruction for which he has been certified.

10. *State Approving Agencies.*—The state agencies to which hospitals should apply for approval as educational institutions are:

Alabama, Montgomery. Department of Education, Mr. E. B. Norton.
Arizona, Phoenix. Department of Public Instruction, Mr. E. D. Ring.
Arkansas, Little Rock. Department of Education, Mr. Ralph B. Jones.
California, Sacramento. Department of Education, Mr. Robert R. Hartzell.
Colorado, Denver. Governor's Advisory Committee on Veterans' Education and Training, Mr. Craig P. Minear.
Connecticut, Hartford. Department of Education, Mr. John E. Nichols.
Delaware, Dover. Board of Education, Dr. H. V. Holloway.
District of Columbia, Washington. Board of Education, Mr. Paul Eddy.
Georgia, Atlanta. Department of Veterans' Education, Capt. F. A. Sams.
Idaho, Boise. Department of Education, Mr. G. C. Sullivan.
Illinois, Springfield. Office of Public Instruction, Mr. Vernon L. Nickell.
Indiana, Indianapolis. Department of Public Instruction, Dr. Clement T. Malan.
Iowa, Des Moines. Department of Public Instruction, Miss Jessie M. Parker.
Kansas, Manhattan. Committee on Institutions for Veteran-Training, Dr. F. D. Farrell.
Kentucky, Frankfort. Department of Education, Dr. R. H. Woods.
Louisiana, Baton Rouge. Department of Education, Mr. Charles B. Manning.
Maine, Augusta. Department of Education, Mr. Harry V. Gilson.
Maryland, Baltimore. Department of Education, Mr. Thomas G. Pullen Jr.
Massachusetts, Boston. Department of Education, Mr. Julius E. Warren.
Michigan, Lansing. Department of Education, Dr. Eugene B. Elliott.
Minnesota, St. Paul. Department of Education, Mr. Dean M. Schweickhard.
Mississippi, Jackson. Department of Education.
Missouri, Jefferson City. Department of Education.
Montana, Helena. Department of Public Instruction, Miss Elizabeth Ireland.
Nebraska, Lincoln. Department of Public Instruction, Mr. Wayne O. Reed.
Nevada, Carson City. Department of Education, Miss Mildred Bray.
New Hampshire, Concord. Board of Education.
New Jersey, Trenton. Department of Economic Development, Mr. Yorke E. Rhodes.
New Mexico, Santa Fe. State Planning Board, Mr. V. J. Jaeger.
New York, Albany. State Education Department, Mr. John S. Allen.
North Carolina, Raleigh. Department of Public Instruction, Dr. Clyde A. Erwin.
North Dakota, Bismarck. Board of Higher Education, Mr. A. F. Arnason.
Ohio, Columbus. Department of Education.
Oklahoma, Oklahoma City. State Certifying Agency, Mr. Milt Phillips.
Oregon, Salem. Department of Education, Mr. Rex Putnam.
Pennsylvania, Harrisburg. Department of Public Instruction, Mr. Paul E. Witmeyer.
Rhode Island, Providence. Department of Education, Dr. James F. Rockett.
South Carolina, Columbia. Department of Education, Mr. W. A. Schiffley.
South Dakota, Pierre. Department of Public Instruction, Mr. J. F. Hines.
Tennessee, Nashville. Department of Education, Mr. Burgin E. Dossett.
Texas, Austin. State Committee for Veterans' Training, Mr. A. O. Willman.
Utah, Salt Lake City. Department of Public Instruction, Mr. E. Allen Bateman.
Vermont, Montpelier. Department of Education, Mr. Ralph E. Noble.
Virginia, Richmond. Board of Education, Dr. J. L. Blair Buck.
Washington, Olympia. Department of Public Instruction, Miss Pearl A. Wanamaker.
West Virginia, Charleston. Department of Education, Mr. W. W. Trent.
Wisconsin, Madison. Veterans' Recognition Board, Mr. Walter B. Senty.
Wyoming, Cheyenne. Department of Education, Esther L. Anderson.
Alaska, Juneau. Department of Education, Dr. James C. Ryan.
Hawaii, Honolulu. Department of Public Instruction, Mr. Orrin W. Robinson.
Panama Canal Zone. Office of the Panama Canal, Mr. B. F. Burdick, Washington, D. C.
Puerto Rico, San Juan. Department of Education, Mr. Jose H. Gallardo.
Virgin Islands, Charlotte Amalie, St. Thomas. Acting Governor of Virgin Islands, Hon. Morris F. DeCastro.

11. *Regional Veterans' Offices.*—The regional offices of the Veterans Administration and veterans' centers having regional office activities are listed here with the name of the manager of the regional office. It is highly important that each participating hospital become well acquainted with its own regional office, its manager and its policies and procedures. It is to this office that the hospital transmits the endorsed Certificate of Eligibility and Entitlement of the resident veteran and presents its claim for remuneration. It is from this office that the hospital and the veteran receive payments.

Alabama, Montgomery. Mr. Middleton E. Head.
Arizona, Tucson. Col. William T. Haraway.
Arkansas, Little Rock. Mr. James A. Winn.
California, Los Angeles, Col. R. A. Bringham; San Francisco, Col. James G. Donnelly.
Colorado, Denver. Mr. A. D. Borden.
Connecticut, Hartford. Mr. Myer Schwolsky.

District of Columbia, Washington. Mr. Howard F. Dickensheets.
Florida, Bay Pines. Mr. M. Bryson.
Georgia, Atlanta. Mr. J. M. Slaton Jr.
Idaho, Boise. Mr. C. H. Hudelson.
Illinois, Hines. Mr. Charles G. Beck.
Indiana, Indianapolis. Mr. B. C. Moore.
Iowa, Des Moines. Mr. William B. Nugent.
Kansas, Wichita. Mr. Leonard N. Sowards.
Kentucky, Lexington. Mr. Harry W. Farmer.
Louisiana, New Orleans. Mr. Frank Martinez Jr.
Maine, Togus. Mr. M. L. Stoddard.
Maryland, Baltimore. Mr. William L. Limburg.
Massachusetts, Boston. Gen. William J. Blake.
Michigan, Dearborn. Mr. Guy F. Palmer.
Minnesota, Minneapolis. Mr. C. D. Hibbard.
Mississippi, Jackson. Mr. W. S. Shipman.
Missouri, Kansas City, Mr. John A. Brody; St. Louis, Mr. Edward J. Wieland.
Montana, Fort Harrison. Dr. Herbert C. Watts.
Nebraska, Lincoln. Mr. E. R. Benke.
Nevada, Reno. Mr. Edward F. Reed.
New Hampshire, Manchester. Mr. James J. Doyle.
New Jersey, Lyons. Lieut. Col. Harold E. Foster.
New Mexico, Albuquerque. Mr. David K. Dalager.
New York, Batavia, Mr. C. F. Sargent; New York, Mr. E. B. Dunkelberger.
North Carolina, Fayetteville. Mr. James S. Pittman.
North Dakota, Fargo. Mr. C. T. Hoverson.
Ohio, Brecksville, Gen. William L. Marlin; Dayton, Mr. John H. Ale.
Oklahoma, Muskogee. Mr. Polk T. Lunquest.
Oregon, Portland. Col. Paul I. Carter.
Pennsylvania, Philadelphia, Mr. H. J. Crosson; Pittsburgh, Mr. Kenneth S. Covey; Wilkes-Barre, Mr. Michael B. Reap.
Rhode Island, Providence. Col. Davis G. Arnold.
South Carolina, Columbia. Mr. S. C. Groeschel.
South Dakota, Sioux Falls. Mr. Charles B. Kaercher.
Tennessee, Murfreesboro. Mr. Sam Jared Jr.
Texas, Waco. Col. Harry Rubin.
Utah, Salt Lake City. Mr. E. A. Littlefield.
Vermont, White River Junction. Mr. Charles L. Jacobs.
Virginia, Roanoke. Col. Edwin W. Jordan.
Washington, Seattle. Mr. O. G. Fairburn.
West Virginia, Huntington. Mr. H. G. Hooks.
Wisconsin, Wood. Mr. Paul G. Froemming.
Wyoming, Cheyenne. Mr. James L. Laughlin.

SUBCOMMITTEE ON VETERANS' AFFAIRS OF THE
COMMITTEE ON POSTWAR MEDICAL SERVICE.
FREDERICK A. COLLER.
J. W. HOLLOWAY JR.
VICTOR JOHNSON.
ALPHONSE M. SCHWITALLA, Chairman.

NAVY

NAVY AWARDS AND COMMENDATIONS

Captain John H. Robbins

The Bronze Star was recently awarded to Capt. John H. Robbins, formerly of Washington, D. C., "for meritorious service in connection with operations against the enemy as force medical officer on the staff of the commander, South Pacific Area and Force, from Feb. 12 to Sept. 26, 1945. During this period Captain Robbins displayed outstanding professional ability in handling the many medical problems which arose in the area. By his initiative and thorough knowledge of medical administration, he maintained an efficient hospital service for the sick and wounded in the South Pacific and from adjacent areas. Through his able supervision of the application of malaria and epidemic control principles, he prevented much loss of manpower from tropical diseases. His leadership and medical skill were in keeping with the highest traditions of the United States Naval Service." Dr. Robbins graduated from Albany Medical College in 1917 and entered the service Feb. 28, 1918.

Commander Hjalmar August Erickson

The Bronze Star was recently awarded to Comdr. Hjalmar August Erickson, Monterey Park, Calif., "for heroic service while attached to the staff of the medical dispensary at Cavite Navy Yard in the the Philippines, during and subsequent to the bombing attack by enemy Japanese forces on Dec. 10, 1941. Although severely wounded when the dispensary received a direct hit, Commander Erickson calmly reorganized the battle dressing station at Porta Vaga Cathedral and, undeterred by the falling of enemy bombs and the resulting fires and explosions, carried on his valiant efforts, administering to over 300 casualties during the afternoon and night without stopping. Through his professional skill and capable leadership many lives were saved, and his indomitable fortitude and unwavering devotion to duty were in keeping with the highest traditions of the United States Naval Service." Dr. Erickson graduated from the College of Medical Evangelists, Los Angeles, in 1923 and entered the service March 14, 1941.

Commander Earle Ellsworth Metcalfe

Comdr. Earle E. Metcalfe, formerly of Washington, D. C., was recently awarded the Bronze Star "for distinguishing himself by meritorious achievement in connection with operations against the enemy during the period May 15, 1945 to Aug. 15, 1945, while serving as senior medical officer of an aircraft carrier. During this period his ship participated in the attack on the islands of Nansei Shoto in support of invasion force, Okinawa, May-June 1945; attack on Tokyo area airfields and on shipping, July 1945; attack on southern Hokkaido airfields, installations and shipping, July 1945; attack on Kure Naval Base and adjoining airfields, July 1945; attack on northern Honshu airfields, August 1945, and attack on Tokyo area airfield, August 1945. He constantly maintained a highly efficient medical department which won the complete confidence of the entire ship's company by its outstanding record of safe recovery for the sick and wounded. His professional skill and able direction of his department in combat operations against the enemy were responsible in a large measure for the maintenance and exceptionally high state of health and morale of the crew and were in keeping with the highest traditions of the United States Naval Service." Dr. Metcalfe graduated from Loyola University School of Medicine, Chicago, in 1936 and entered the service Nov. 11, 1937.

Lieutenant (jg) Charles Arthur Dwyer Jr.

The Bronze Star was recently awarded to Lieut. (jg) Charles Arthur Dwyer Jr., formerly of Houston, Texas, "for meritorious achievement as attending surgeon in the Isolation Department and later as a ward surgeon at the Billibid Hospital for Military Prison Camps, Manila, Philippine Islands, from Oct. 30, 1944 until the recapture of that prison by American forces on Feb. 4, 1945." The citation stated that, "although himself a patient in the hospital, Lieutenant Dwyer voluntarily returned to a duty status and, overcoming severe handicaps to efficient treatment, including miserable living conditions, diet deficiencies and inadequate supplies and equipment, afforded those in the compound full benefit of his surgical skill and excellent critical analysis of each case, laboring long hours to examine as many as 300 patients in the morning and an equal number at evening sick call. Acting also as the activity's admitting officer at a time when all personnel suffered from malnutrition, he carefully considered all applicants for admission and chose the most serious cases to occupy the limited bed space available, basing his individual judgment on the best interests of all. Through his consistently cheerful demeanor, unwavering concern for the welfare of others and extraordinary professional ability, Lieutenant Dwyer contributed immeasurably to the maintenance of morale at Billibid and to the successful functioning of the vital Medical Detachment." Dr. Dwyer graduated from Louisiana State University School of Medicine, New Orleans, in 1939 and entered the service in March 1942.

Lieutenant Commander James S. Vedder

The Silver Star was recently awarded to Lieut. Comdr. James S. Vedder, formerly of Marshfield, Wis., for "gallantry in action" while serving as battalion surgeon of the 27th Marine Regiment during the Iwo Jima campaign. Dr. Vedder graduated from Northwestern University Medical School, Chicago, in 1938 and entered the service Sept. 24, 1942.

ARMY

OBSERVE FOURTH ANNIVERSARY OF O'REILLY GENERAL HOSPITAL

During the past four years more than 16,000 surgical operations have been performed at the O'Reilly General Hospital, Springfield, Mo. The Medical Department Enlisted Technicians School at O'Reilly General Hospital has graduated more than 14,000 technically trained medical corpsmen and, in addition, courses have been conducted for orthopedic mechanics, anesthetists, physical therapy aides, hospital dietitians and x-ray, laboratory and occupational therapy technicians.

At the ceremony celebrating the fourth anniversary of the hospital Commanding General George B. Foster paid high tribute to the officers, nurses, enlisted men and women and the civilians who have served at O'Reilly and publicly acknowledged his gratitude for the loyalty, fidelity, cooperativeness and selfless devotion to duty which they displayed at all times.

NEW DIRECTOR OF OCCUPATIONAL THERAPY DIVISION

Miss H. Elizabeth Messick, former director of occupational therapy for the District of Columbia Health Department, was recently appointed director of the Occupational Therapy Branch, Reconditioning Consultants Division, Office of the Surgeon General, succeeding Mrs. Winifred G. Kahmann, who is returning to her former position as director of occupational therapy at the Indiana University medical center, where she served eighteen years before coming to Washington. Miss Messick served as a member of the Walter Reed staff from 1933 to 1939. In 1939 she organized and developed a department of occupational therapy under the Bureau of Maternal and Child Welfare of the District of Columbia Health Department. She came to the Office of the Surgeon General in 1944, where she was appointed assistant chief of the Occupational Therapy Branch, Reconditioning Consultants Division.

VISIT PACIFIC ARMY HOSPITALS

Brig. Gen. Hugh J. Morgan, director of Medical Consultants Division, and Col. Francis R. Dieuaide, chief of Tropical Disease Treatment Branch, are making an inspection of medical services in the Pacific, Japan and Japanese territory and surveying problems concerned with internal medicine. During a two week stopover in Manila a special study was made of the comparison between patients from Asia suffering starvation and Europe's starvation cases.

Health studies were recently made in Europe by Brig. Gen. James S. Simmons, chief of Preventive Medicine Service, and Col. Thomas B. Turner, director of Civil Public Health and Nutrition.

RECEIVES ITALIAN AWARD

Major Dallas G. Baynton, A. N. C., Chicago, was recently awarded the Cross for War Merit by the Italian government. Major Baynton has been a member of the Army Nurse Corps since 1942.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel William B. McCutcheon

Lieut. Col. William B. McCutcheon, formerly of Durham, N. C., was recently cited for "meritorious service from Aug. 11, 1944 to May 4, 1945. As chief of surgical service of the 101st (U. S.) General Hospital, Lieutenant Colonel McCutcheon's knowledge and skill of surgery contributed in a marked degree to the successful and high professional standards attained in adequately providing for the sick and wounded. Displaying unusual qualities of leadership and untiring devotion to duty, he achieved remarkable results under capacity conditions. The meritorious services rendered by Lieutenant Colonel McCutcheon are in keeping with the high standards of the military service." Dr. McCutcheon graduated from the Medical College of Virginia, Richmond, in 1921 and entered the service May 11, 1942.

Lieutenant Colonel Oscar P. Hampton Jr.

The Legion of Merit was recently awarded to Lieut. Col. Oscar P. Hampton Jr., formerly of University City, Mo., for performance of outstanding services in North Africa and Italy as consultant in orthopedic surgery. The citation reads, in part, "Colonel Hampton early in the Tunisian campaign observed that the prevalent and widely accepted method for the management of battle fractures should be abandoned and more radical but correspondingly more successful procedures substituted therefor. Energetically pursuing this line of development, with the adjuvant use of penicillin during the Italian campaign the surgical management of the compound fracture of warfare was revolutionized. An exponent of complete initial surgery followed by precise reparative surgery, Lieutenant Colonel Hampton extended his teachings on a theaterwide basis, and by precept and demonstration he furthered a program that materially reduced the incidence of the crippling or even fatal infection that so readily converted this common battlefield wound into a major catastrophe." Dr. Hampton graduated from the University of Tennessee College of Medicine, Memphis, in 1928 and entered the service Jan. 10, 1942.

Major Richard V. Ebert

The Bronze Star was recently awarded to Major Richard V. Ebert, formerly of Brookline, Mass., "for meritorious service in connection with military operations as a member of the Medical Service of the 5th General Hospital from May 12, 1942 to May 15, 1944. Major Ebert demonstrated great ingenuity in collaborating with another officer in developing a simple, practical and easily operated transfusion apparatus for field use. This device has proved to be an invaluable contribution to the Medical Department's field equipment and makes whole blood transfusions easily and readily available to the wounded in forward echelons. Major Ebert's device has been of great value to the success of military operations and has saved the lives of countless soldiers." Dr. Ebert graduated from the University of Chicago School of Medicine in 1937 and entered the service Jan. 1, 1942.

Captain Stanley K. Gutelius

The Bronze Star was recently awarded to Capt. Stanley K. Gutelius, formerly of Rochester, N. Y. He was further cited for his initiative, zeal and professional skill necessary to the successful accomplishment of his battalion's missions. "His untiring efforts in caring for the sick and wounded are reflected in the high standard of health and morale maintained in his unit despite weather and obstacles incident to combat." Dr. Gutelius graduated from the University of Michigan Medical School, Ann Arbor, in 1941 and entered the service Sept. 5, 1942.

Captain Carl Milchen

Capt. Carl Milchen, formerly of Blair, Wis., was recently awarded the Bronze Star "for meritorious achievement in connection with military operations against the enemy at Leyte Province and Luzon Island, Philippine Islands, from Oct. 20, 1944 to May 21, 1945." Dr. Milchen graduated from Marquette University School of Medicine, Milwaukee, in 1937 and entered the service Aug. 17, 1942.

Major Meyer Maskin

Major Meyer Maskin, New York, was recently awarded the Bronze Star and Bronze Arrowhead. He served as psychiatrist with the 4th Infantry Division in the European Theater of Operations. Dr. Maskin graduated from Wayne University College of Medicine, Detroit, in 1935 and entered the service May 15, 1942.

Lieutenant Colonel Maurice A. Hardgrove

Lieut. Col. Maurice A. Hardgrove, formerly of Milwaukee, was recently awarded the Legion of Merit for "exceptionally meritorious conduct in the performance of outstanding service." Dr. Hardgrove graduated from Columbia University College of Physicians and Surgeons, New York, in 1928 and entered the service July 2, 1942.

ORGANIZATION SECTION

Postwar Medical Service

MEETING OF DECEMBER 1, 1945

The Committee on Postwar Medical Service was called to order by the Chairman, Dr. Ernest E. Irons, at 10:04 a. m., Saturday, Dec. 1, 1945, in the Board of Trustees Room at American Medical Association Headquarters in Chicago. The following members and liaison members of the committee and guests were present:

Dr. Irvin Abell.
Dr. Arthur W. Allen.
Dr. Louis H. Bauer.
Dr. Walter L. Bierring.
Dr. James R. Bloss.
Dr. Willard Camalier.
Dr. Frederick A. Coller.
Mr. Graham L. Davis.
Capt. William E. Eaton.
Lieut. Col. Bryan C. T. Fenton.
Dr. Ralph Fenton.
Dr. Morris Fishbein.
Dr. Evarts A. Graham.
Lieut. Comdr. G. G. Gross.
Capt. L. M. Harris.
Dr. E. L. Henderson.
Mr. T. A. Hendricks.
Mr. J. W. Holloway Jr.
Dr. Ernest E. Irons.
Dr. Victor Johnson.
Col. B. R. Kirklin.
Dr. Herman L. Kretschmer.
Major Gen. George F. Lull.
Dr. James M. Mason.
Col. Hugo Mella.
Dr. J. J. Moore.
Dr. Howard C. Naffziger.
Dr. James E. Paullin.
Dr. Robert A. Peers.
Lieut. Col. William N. Piper.
Dr. C. W. Roberts.
Alphonse M. Schwitalla, S.J.
Dr. R. L. Sensenich.
Lieut. Col. Rolland B. Sigafoos.
Dr. H. H. Shoulders.
Dr. LeRoy H. Sloan.
Dr. Austin E. Smith.
Miss Mary Switzer.
Dr. Olin West.

SURPLUS MEDICAL AND HOSPITAL SUPPLIES

Father Schwitalla, chairman of the Subcommittee on Surplus Medical and Hospital Supplies, presented a progress report, which, after discussion, was adopted and publication authorized. (The report was published in The Journal Dec. 8, 1945, p. 1033.)

Dr. Camalier stated that the American Dental Association feels that the veteran is not getting what he is entitled to under the law. His association feels that the dental veteran will produce more in the cause of public health and more directly and more quickly than the state and municipal agencies, which, under the law, will have first priority. Under the program being considered the hospitals and dental offices to be established in thousands of communities will take a long time and the surplus dental equipment now available will not be worth anything by the time they are made available. Father Schwitalla stated that he thought the veteran was being given as much preference as could be given him under the existing law.

Dr. Camalier moved that the Committee on Postwar Medical Service go on record as favoring a number 1 priority for medical and dental veterans for obtaining surplus material, whether it requires a liberal interpretation of the regulations or a change in the law. The motion was seconded and an amendment offered providing that regulation No. 14 should be left intact. Action on the motion was postponed until later in the meeting.

EDUCATIONAL INTERNSHIP AND RESIDENCY OPPORTUNITIES FOR MEDICAL OFFICERS

Dr. Johnson presented the following progress report:

> Large numbers of medical officers are seeking residencies especially in surgery. Many of them communicate with the Council on Medical Education and Hospitals and many more with hospitals directly. The following suggestions have been helpful to returning medical officers: First they are urged to seek appointments in hospitals in which they may formerly have carried out some house officer work. Secondly they are urged not to insist that the residency be in a medical school hospital but should be sought in some other approved residency hospital, at least for a time.
>
> The Council on Medical Education and Hospitals has inaugurated a card reporting system by means of which hospitals report vacancies at regular intervals in all fields for which they are approved. This reporting system has been extremely valuable in advising returning medical officers of hospital vacancies.
>
> The Council is attempting to work out with the specialty boards a streamlined system of approving new residencies on a provisional or probationary basis. This should make available more rapidly new residency openings, which are being developed in considerable numbers.
>
> The Selective Service System has made a ruling which will make it possible for medical schools to return to autumn admissions of freshmen classes if they so desire even though the current academic year in the school may end in April. This rule was designed to permit certain medical schools which wish to do so to free all their clinical facilities for the instruction of veterans for a period of three to six months next spring or summer. As far as the Selective Service System and the Navy are concerned, schools may now plan this if they wish. The Army has taken the stand that such deceleration may not take place so long as there are army students in the medical schools. Efforts are being made at acquainting the Army with the importance of making an adjustment similar to that of the Navy and the Selective Service System.
>
> The Procurement and Assignment Service will discontinue the deferment of reserve officers of the Army Specialized Training and Navy V-12 programs beyond a twelve month internship effective April 1, 1946. This should make many more residencies available to returning medical officers.
>
> The demand for reprints of "Continuation Courses for Veteran and Civilian Physicians" has been very great. Nearly a thousand copies are distributed each month in response to requests for this information. The list of continuation courses being offered from Jan. 1 to July 16, 1946 will be published in The Journal Dec. 8, 1945. This list is about 30 per cent longer than for the preceding period. There are more courses of longer duration and more courses being offered by universities and medical schools, and there is a broader geographic distribution.

At the request of Dr. Graham, Dr. Johnson read an excerpt from a directive issued by the Procurement and Assignment Service under date of Nov. 6, 1945, as follows:

> In the interest of adequate distribution of the available supply of veterans, it is expected that hospitals will not fill their house staffs out of proportion to present quotas.

Dr. Graham moved that the Committee on Postwar Medical Service protest most violently against the intolerable situation which that portion of the directive imposes. After extended discussion, during which Miss Switzer stated that it was unfortunate that that particular portion of the directive should have been so worded but that she did not think it needed be taken too seriously, no action was taken on the motion, and Dr. Johnson's report was adopted. Dr. Graham then moved that the committee go on record as favoring taking returning medical officers for residencies in teaching hospitals approved for residencies by the American Medical Association in as great numbers as possible. Dr. Johnson added to the motion, with Dr. Graham's consent, "and without any kind of quota limitation." The motion was adopted unanimously after extended discussion.

There was lengthy discussion on the subject of the deceleration of the medical school curriculums, mentioned in Dr. Johnson's report, and Father Schwitalla moved that Dr. Johnson be asked to present to the executive committee of the Association of American Medical Colleges for its discussion and action a request that the War Department be asked to discontinue its Army Specialized Training Program at the end of each school's current session. The Chairman suggested amendment of the motion by adding "and, in the event of the College Association taking favorable action on the request, that that association take up the matter directly with the War Department." The motion, seconded by Dr. Bierring, was adopted.

BUREAU OF INFORMATION

Dr. West presented a report on the activities of the Bureau of Information, which follows in condensed form:

> Since V-J day the Bureau of Information has received each week about 565 letters from medical officers, and a weekly average of 110 physicians have come to the office for specific information regarding medical education, licensure and relocation.
>
> One of the important objectives of the Bureau of Information has been to assist the returning doctor to make a wise selection of a community in which to reestablish his practice. Medical officers contacting the Bureau for information regarding opportunities in certain states are furnished with complete listings of the areas in the states where there is need for a physician. For further information regarding the establishment of a practice in certain areas they are referred to the secretaries of the county and state medical societies.
>
> There appears to be among the returning veterans a trend to get away from the rush and tension of practice in large urban centers. It is felt that through the cooperation of the smaller communities in attracting physicians to their areas by offering them better hospital facilities and through an organized grouping of the physicians' services in health centers there will be little difficulty in getting the physician

seeking a place to reestablish his practice to go into areas where he is most needed.

Another objective of the Bureau of Information has been to have at the central office up to date statistics of the medical facilities for each area in the country. At present there is a permanent card file for the 3,072 counties in the United States giving important data concerning the unit, the county. There are still 551 counties that have not returned the completed summary sheets for their areas. Considering the many changes that have been taking place since V-J day and the importance of having accurate statistics at the central office of the Bureau, a memorandum will soon be sent through the state medical offices to the secretaries of the county medical societies giving the distribution of physicians for their counties as recorded at the Bureau and requesting the secretaries to make any changes necessary so that the Bureau may have a picture of the medical personnel in their areas and of the present and future needs for the adequate medical care of their community. It is the plan of the Bureau, when the physicians who were in practice before entering the armed services have returned to their civilian practices again, to publish in The Journal periodically a map of the United States showing the physician-population ratio for each county. From time to time the Bureau will continue to publish in The Journal certain data regarding the medical and economic aspects of certain areas.

With the cooperation of all who are so vitally interested in furthering the better distribution of physicians through the timely efforts of the Bureau of Information, it is felt that the first basic point of President Truman's recent recommendation to Congress that there be a better distribution of physicians throughout the country and that physicians seeking locations to practice be encouraged to locate in areas where they are most needed can be worked out successfully.

The Council on Medical Education and Hospitals receives approximately 1,200 letters a month from physician veterans and medical officers on active duty. Most of the officers seek information on residencies in specialties, short term refresher courses, basic science instruction and other matters relating to the education of physician veterans under the G. I. Bill of Rights. Numerous requests are also received with reference to specialty certification, requirements of the individual boards, educational credit for military service, opportunities for training in army, navy and veterans' hospitals, preceptorships and assistantships, affiliated hospital assignments, quota allocations and deferment of residents and assistant residents under the 9-9-9 program of medical education. Several seek information on hospital administration, medical licensure requirements, opportunities for staff appointments, organization of clinics, office plans, surplus equipment and supplies, financial aids in training and practice, suitable appointments for handicapped veterans and various other questions.

All inquiries receive careful attention, and every effort is made to supply complete information to all medical officers. In relation to educational opportunities, the Council provides lists of postgraduate continuation courses for veteran and civilian physicians, hospitals approved for internships, residencies and fellowships, and lists of vacancies reported in relation to individual specialties. Since Oct. 18, 1945 the Council has conducted two surveys to ascertain the number of vacancies available in approved hospitals for returning medical officers. The Council is also continuing its efforts to establish additional high grade residency programs in hospitals that have not yet developed their educational service to full capacity. Through these activities many new services are now in process of organization and may soon be added to the approved lists.

Approximately 200 medical officers visit the Council's office each month, seeking in general the same type of information as requested in the letters already mentioned. Among these men there is great interest in certification and specialty practice, although the older group, 35 to 40 or over, hesitate as a rule to undertake a long term residency program of three years to qualify for board certification. Many of these, however, are hoping to obtain assistantships or preceptorships that combine both practice and education and at the same time afford greater financial aid. Some officers are undecided as to future training and practice and appreciate very much the assistance that our office is able to give through personal counseling. A considerable number of the officers are critical of their army service and some are disappointed that educational appointments are not immediately available for residency or postgraduate training. It is observed, however, that the great majority are applying at university hospitals or medical centers, where requests for training are already in excess of available facilities.

The personal interviews have been exceedingly helpful in relation to these problems. The medical officers appreciate the opportunity to express their views, and it is also possible in these contacts to explain more fully the work of the American Medical Association in connection with graduate and postgraduate medical education. The value of these contacts is clearly evident, and every effort will be made to continue our assistance and personal service to the returning medical officer.

The Bureau of Legal Medicine and Legislation has actively cooperated with the Bureau of Information in the accomplishment of the duties devolved on it. The Bureau assisted in the preparation of the Information Bulletin for Medical Officers, has answered by correspondence a considerable number of inquiries relating to problems of medical licensure and to the benefits available to medical officers under the G. I. Bill of Rights, and has accorded interviews to medical officers who have visited headquarters in person seeking information on licensure, on the G. I. Bill of Rights and on partnership agreements. Additionally, many telephone inquiries have been answered. About a week ago the Director furnished Mrs. Shuler with statistics indicating the number of inquiries answered for the Bureau of Information, a minimum of 294.

The inquiries answered during the last several months have been fairly evenly divided between licensure problems and benefits under the G. I. Bill of Rights. As to licensure problems, medical officers are concerned mainly with the problem of obtaining reciprocity licenses. Many feel that service in the military forces should constitute a qualifying factor for the obtaining of licenses by reciprocity. Relatively few inquiries have been received from medical officers who entered service without obtaining a license in any state. A much larger number have come in from graduates of unapproved schools, and these inquiries indicate a feeling that military service should qualify such graduates for licenses in states that otherwise would not consider their applications because of their school of graduation.

As to the benefits accorded by the G. I. Bill of Rights, medical officers are concerned with the maintenance allowance provided by the federal law, with whether benefits will be available during the terminal leave period, with whether benefits will be available while serving residencies and the relationship to such benefits of stipends paid by a hospital, with the procedure to be followed in taking advantage of the loan provisions of the federal law and with the procedure that a medical officer must follow in making application for benefits generally.

It was moved by Dr. Paullin that the Committee on Postwar Medical Service request the Board of Trustees of the American Medical Association to authorize the continuance of the Bureau of Information beyond the time originally contemplated, and the motion was adopted.

GRADUATE MEDICAL EDUCATION IN NAVAL HOSPITALS

Captain Eaton was requested to give the Committee a résumé of the Navy's program with respect to internships, residencies and graduate medical education, and he presented Captain Harris, who submitted the following memorandums. Captain Harris stated that the memorandum on postgraduate medical education had been prepared by Commodore Alphonse McMahon (MC), U.S.N.R.

Graduate Medical Education in Naval Hospitals.—The overall program for graduate medical education in the Navy should include an advisory committee or board consisting of reserve officers who are outstanding in their own special fields. This board or committee should be under the direct control of the Surgeon General and be responsible to him. In the formative period they can be given charge of developing their own specialties in the different centers. They can select instructors and outline the policy of the teaching of their particular specialties in all the centers. They can confer with their specialty boards in regard to the certification of medical officers and, if necessary, arrange for special certification of navy personnel. This has already been suggested by the orthopedists themselves and has been taken under advisement. This advisory board should meet with the Surgeon General at least once a month for the first year in order that this program can be followed closely and necessary changes made to fit the needs of the various centers. It is conceivable that lack of clinical material may handicap the teaching of a certain specialty in certain hospitals. Either more clinical material should be sent to this center or the teaching of the specialty should be discontinued or transferred to another hospital.

Graduate education in naval hospitals must of necessity be divided into three main divisions: The first division has to do with the eight hospitals which have been selected as centers for the teaching of specialties. It is proposed that these centers be set up at Chelsea, St. Albans, Philadelphia, Bethesda, Great Lakes, Long Beach, Oakland and Seattle. These hospitals have already been approved by the American College of Surgeons and some of them by the Council on Medical Education and Hospitals. It is proposed to set up teaching services in these hospitals, planned and executed along the lines of the teaching services in civilian hospitals. These services will be set up with interns, assistant residents and residents who will run the service under the direction of the attending instructor, who, in turn, will govern the policy of the service and supervise the activities. These centers have been selected with regard to geographic distribution and proximity to teaching institutions and medical centers. Reserve medical officers who have been on active duty will be requested to serve as consultants as far as possible. The orthopedic committee on education is setting up teaching centers in the various areas in civilian hospitals and has offered to include naval hospitals in its consideration. By accepting this offer we shall be saved the necessity of setting up our own teaching service. Another advantage to this type of teaching service is that it offers a medical officer in the Navy the same training he would have received in civilian hospitals. It is hoped that other specialties will follow the example of the orthopedic committee.

The second division of graduate medical education in the Navy has to do with the hospitals not included in the aforementioned centers, where, unless teaching services are established, the medical officers will feel that they are being neglected. In considering plans for instruction in medicine, surgery and the specialties in these hospitals, it is suggested that every effort be made to place qualified men as chiefs of service. It may be necessary to send the qualified surgeons and internists to these hospitals in preference to the centers because of their ability to set up teaching services. Thus it would be possible to give courses in these hospitals in internal medicine, general surgery, eye, ear, nose and throat and neuropsychiatry which would fit in with the plan in the first division for training in the special services. Thus a man could take either his internship or first year of residency in these hospitals and be transferred to the centers for his special training in orthopedics, plastic surgery or other subject. By combining Division I and Division II, a comprehensive graduate course can be set up in which no discrimination will be made against the men ordered to hospitals other than the teaching centers.

Division III of the educational program involves *teaching in civilian* hospitals, universities and foundations. In order to complement the first two divisions in the program, a survey should be made of teaching *fellowships* available to officers of the regular Navy. The criticism has been made with regard to prewar training in civilian institutions that *six months or even a year is too short a time in which to become* proficient in *any specialty. It may be necessary to extend the time in* civilian hospitals or to make *training in civilian hospitals a part of the* overall program for training in the specialties. Thus a medical officer could take his internship and one or two years' *residency* in naval *hospitals* and after he returns from sea duty be assigned to a civilian institution for graduate instruction in orthopedic or plastic surgery. In this way the three divisions will be integrated and *there will be no loss* of time, expense or motion in carrying out the program.

In addition to these three divisions the course at the Naval Medical Center in Bethesda should be used for indoctrination and special courses in laboratory and tropical medicine.

Postgraduate Medical Education in the Navy.—The Navy Department established the V-12 Program in March 1943 effecting the enlistment and assignment of personnel to active duty in a training capacity on July 1, *1943. This program was established* in order to assure a continuous flow of medical students deferring them from Selective Service and assuring a continuous flow of medical *officers of the Naval Reserve for assignment* to active duty for naval intern training or on the completion of civilian training. There were approximately 5,000 Ensigns H(P), U. S. N. R., serving on inactive duty as medical students who were automatically enlisted in class V-12 on the submission of resignations from their inactive Reserve status. This was a voluntary procedure, and approximately *99* per cent of all Ensigns H(P), U. S. N. R. (Medical), were enlisted in the *V-12 Medical Program.*

At the present time there are approximately 6,800 V-12 medical students *enrolled* in the *Navy College Training Program. The Navy* Department on Sept. 1, 1945 informed all medical schools that it was the *intention to place all V-12 medical students on inactive duty on the completion of the present semester.* By March 15, 1946 all V-12 medical students will have been placed on inactive duty. These students will then be required to pay all expenses, tuition, and so on, as the government is no longer responsible for any financial obligations incurred by these students. The records indicate that 3,616 medical students have graduated from the program and at present hold appointments as Lieutenants (jg) (MC), U. S. N. R.

It is the intention of the Navy Department to continue to defer from call to active duty V-12 medical students until such time as they have graduated, been appointed as Lieutenants (jg) (MC), U. S. N. R., and have completed *civilian intern training.* V-12 graduates who qualify for naval internships will be ordered to active duty as Lieutenants (jg) (MC), U. S. N. R., on graduation. Medical Reserve officers will be ordered to active duty on the completion of intern training *up to* and including six months after the termination of the present national emergency. Assignments to active duty after that date must be on a voluntary basis for Reserve officers.

The 9-9-9 Program *was accomplished by the Procurement and Assignment* Service for Physicians, Dentists and Veterinarians in cooperation with the Surgeons General of the *Army and Navy. In brief,* the function of the 9-9-9 Program was predicated on the assumption that an *insufficient number* of civilian interns would be available unless the Army and Navy agreed to defer from call to active duty a certain percentage of all medical officers graduating in *the military training programs.* The Surgeons General of the Army and Navy agreed to recommend the deferment of one third of all Reserve medical officers completing nine months of intern training *to* serve as junior residents in civilian hospitals. Under this program one half of the one third interns referred to were recommended for an additional deferment of *nine months in order* to serve as senior residents in civilian hospitals. At the present time there are *766 Naval Reserve* medical officers serving junior residencies and 135 serving senior residencies in civilian hospitals.

It is anticipated by the Bureau of Medicine and Surgery that the 9-9-9 Program will be revised in the near future. It is believed that under this revision Reserve medical officers will become available for active duty after they have completed twelve months *of intern training.* In this regard it may be necessary to extend the deferment of Reserve medical officers for the *period April 1, 1946 until July 1, 1946* as an overlapping period, the legal internship of twelve months to begin on *July 1, 1946.* If this is accomplished, V-12 medical students graduating on or about April 1, 1946 would be deferred from call to active duty *until July 1, 1947.* It is the understanding that all civilian hospitals will revert to the twelve month intern schedule commencing *July 1, 1946.* It is the intention of the Navy that the present intern schedule of nine months be *modified to* the prewar schedule of *twelve months of* intern training. It is anticipated that this will be effected April 1, 1946.

Postgraduate medical education in the Navy is recognized as being an *essential feature* of postwar plans. To maintain the high standards in the practice of *medicine* this training is of paramount importance to men who have received their medical education under the accelerative instructional *plan* of medical schools and hospitals. Furthermore, specialization has been *recognized* in the Navy, and opportunities *to become proficient* in *the various* medical specialties will be provided for the men in the Medical Corps. Realizing that *not every naval* hospital can be set up as a center for postgraduate medical education, eight naval hospitals will be maintained *as centers for* postgraduate medical training and services will be organized in these hospitals similar to the arrangements for *resident training* in universities and civilian hospitals. In addition to the regular staff of medical officers *in these* eight educational centers, certain *outstanding* authorities in the various specialties among the Naval Reserve officers will be invited to serve on the *staff as consultants and attending physicians.* These men will not only serve as consultants for *problem cases* but also organize the teaching *of their* individual specialties *with* ward round seminars and departmental meetings to *further* the teaching program. A definite head of *the training program is to be set up in the Bureau of Medicine* and *Surgery* and in addition an advisory committee consisting of the Reserve consultants will supervise and help *organize the teaching in these centers. These Reserve* consultants *will be selected by* and act as consultants to the Surgeon General while serving in this capacity. With this *type of organization it is* possible to maintain these centers so that *the courses are coordinated, allowing* the transfer of men from one center *to* another without interrupting the overall program of their training. The program for the training *of younger* men in the Naval Medical Corps will consist of a *five year period, during* which time the medical officer will be assured of his *internship* and one or two years of resident training. In view of the fact that sea duty is *necessary to maintain the* Medical *Department afloat,* this must be included in the program. During the customary two years at sea, one year at least will be *spent either on a hospital ship or on duty* at some overseas base, and one year will be used aboard battleships, *cruisers* and *other* vessels. Following the tour of sea duty the young *medical officer will* return to one *of* the training centers for at least two years of intensive work in the *specialty which has been* decided on by the Advisory Board *following his request for further* training. At the present time these postgraduate training centers *are being planned at Chelsea, Mass., St. Albans, L. I., N. Y., Philadelphia,* Bethesda, Md., Great Lakes, Ill., *Long Beach, Calif., Oakland, Calif.,* and Seattle. Not all centers will have *training in all the specialties and* the selection of the specialty will depend on available clinical *material* and competent instruction. In view of the fact that civilian *residencies* and fellowships are designed primarily to meet the requirements for certification of special practice, these requirements are to be met at the training center. The availability of veterans as patients in these training centers will increase the clinical scope and *allow for better overall teaching. It is contemplated that these* training centers will develop into as valuable opportunities for postgraduate study as the present teaching plans of *universities and other centers of medical* education.

A word should be said concerning the sea bases at which hospitals are maintained where courses of instruction will be *carried out as far as* possible. We *shall* have *bases in the Hawaiian Islands the Marianas* the Philippines the Canal Zone, San Juan, Puerto Rico and Guantanamo Cuba. In addition to these there will be four hospital ships on which training will be given. Complete records of attendance on these courses *will be* maintained at the *Bureau* of Medicine and Surgery for the convenience of giving credit for these courses as well as *for* assisting in *planning and arranging for the courses. Thus, a young medical officer* who enters the Navy will immediately enter on a postgraduate course over a period of five years. Instruction will be provided in all of the American Board specialties. His course will be planned in the Bureau of Medicine and Surgery, and definite time will be allotted for his participation in these courses. On completion of sea duty he is to return to one of the centers for further instruction in the specialty which he has requested and which has been approved by the Board.

It is conceivable and probable that places for instruction will not be available *for all the members of the Hospital Corps. Therefore* the *men* will be selected according to their aptitude, their industry and their interest in the specialty which they have chosen. In setting up these centers opportunities will be given to men who prove themselves worthy of further instruction, and every effort will be made to provide them with courses of instruction which meet the requirements of the different medical organizations and specialty *boards* and equal to or superior to those which they could obtain in civilian life.

ENROLMENT OF MEDICAL STUDENTS

Dr. Johnson, chairman of the Subcommittee on Enrolment of Medical Students, *submitted the following progress report:*

Dr. Harold Diehl of the Procurement and Assignment Service has collected data from twelve colleges and universities which in 1942 supplied *about 10 per* cent of medical school freshmen. Premedical enrolments in these schools indicate that an entirely inadequate number of freshmen of good quality *will* be available for 1946 freshmen *medical* classes.

This problem is scheduled for immediate consideration by *the* new committee on deferments of the Office of War *Mobilization and* Reconversion. Even if deferments should be made *now,* it is already too late *to provide many students for the 1946* entering classes but such deferments would materially improve conditions for *1947.*

This subcommittee and the Council on Medical Education and Hospitals have recommended that qualified men in the armed *forces* should be released for premedical studies and that qualified civilians should be deferred. These recommendations have also been *made to* the Senate Committee on Military Affairs by Col. W. Paul Holbrook who was *appointed by the Senate committee to study this problem.* There is now some indication that the Selective Service System and the Army may be ready to move in the recommended direction in the near future. We are recommending to the *Selective Service System* that men in science studies including premedicine on reaching the age of 18 should be deferred until the completion of the *academic year. This would assist* materially, since further adjustments might be possible at that time.

The progress report was adopted after discussion.

VETERANS ADMINISTRATION

Father Schwitalla, chairman *of the Subcommittee on* Establishment of Medical Corps in the Veterans Administration, reported on *the bills before Congress* with reference to reorganization of the Veterans Administration.

The Committee adopted a motion that the subcommittee be empowered to pursue its efforts toward the establishment of a commissioned medical corps in the Veterans Administration.

EDUCATIONAL PROGRAM UNDER THE G I BILL OF RIGHTS

Father Schwitalla, chairman of the Subcommittee to Confer and Cooperate with the Veterans Administration, presented the following report

The Subcommittee to Confer and Cooperate with the Veterans Administration on the educational program under the G I bill is made up of Dr Coller and myself We have been fortunate however, in having the assistance of Dr Victor Johnson I have attempted to contact Dr Coller at the various stages which I am about to report but have not succeeded in all instances I have his assurance that I am free to mention any of the matters pertaining to the developments which have taken place even of those concerning which I have not been able to consult him

Shortly after the last meeting of this committee on September 22, word was received from Mr Sidney Post Simpson, educational adviser on veterans programs of the Practicing Law Institute, New York City The practicing Law Institute acted as spokesman for the American Bar Association the American Institute of Accountants and probably for the American Institute of Banking with reference to the proposed amendments to the G I bill as embodied in H. R 3749 Mr Simpson suggested that the amendments to the bill which he was advocating on behalf of his principals were such as probably would commend themselves to the American Medical Association and he inquired whether the American Medical Association would join in endorsement of the proposed amendments to Public Law 346 The amendments pertain chiefly to the amount of tuition payable under the act, subsistence and travel allowances correspondence courses books for home study, et cetera After reaching Dr Coller and Dr Johnson by telephone it was agreed first that a telegram be sent to Mr Simpson, secondly that we request Hon Edwin C Johnson of Colorado chairman of the Senate Subcommittee on Veterans' Legislation, to permit us to file a statement on behalf of the American Medical Association even at the last minute prior to the publication of the proceedings of the hearings on the G I bill which would be held in Washington and, thirdly, that a draft be prepared immediately expressing the interest of the medical profession in the proposed amendments particularly as far as these have a bearing on the educational opportunities for physician veterans The following telegram was sent to Mr Simpson

'The educational problems of the medical profession with reference to the G I Bill are substantially similar to the educational problems of the legal profession If the subcommittee on the Veterans Educational Program of the Committee on Postwar Medical Service of the American Medical Association had the opportunity of presenting its points of view, these would be found to be in substantial agreement with the views expressed in the document 'educational needs of lawyer veterans' It is still the hope of the medical group that some of its problems can be solved by changes in the regulations It may well be however that, to effect certain desirable changes amended legislation may be necessary "

With reference to the second point, the hearings before the Senate subcommittee were held October 8 to 12 inclusive It was not possible at the time to secure representation for the Committee on Postwar Medical Service, and some time had to elapse before an adequate statement could be prepared Fortunately, Senator Johnson agreed to embody any statement made by our subcommittee in the protocol of his hearings

Accordingly, a statement was prepared by the subcommittee at a special meeting in Chicago at the headquarters of the American Medical Association on October 19 After presenting facts concerning the competence of the subcommittee to represent the Committee on Postwar Medical Service the statement requests that legislation be clarified with reference to '(a) the recognition of the hospital as an educational institution for the education of residents and (b) the recognition of the resident as a student of medicine rather than only as a professional person giving service to the hospital or to the patients in the hospital' Five amendments to the present G I bill are requested at the end of the presentation·

1 That there be introduced into the act, wherever such introduction is proper, a word or words to indicate that the hospital is an educational institution with reference to the objectives of Public Law 346 or any amendments or developments of it,

2 That physician veterans acting as residents in properly approved hospitals be recognized as "students, again within the objectives of Public Law 346 and that, accordingly, hospitals should be entitled to tuition payments for the education of such residents,

That all physician veterans be declared eligible for the educational benefits conferred by the amended G I act irrespective of their age and even though they have been holders of the M D degree for years, in other words that any restrictions such as that now contained in the regulations requesting proof that the veteran's education has been interrupted by the war should be eliminated,

4 That refresher courses should be paid for on the basis of the tuition charges made by the institution and such payments should not be limited by such restrictions as are now found in the regulations,

5 That a declaration be included in the amendments permitting physician veterans to participate in the educational benefits by beginning their studies even during their terminal leave and before the date of their actual discharge

The entire document with its recommendations was actually printed in a public document entitled "Amendments to the Servicemen s Readjustment Act of 1944 Hearings before a Subcommittee on Finance, United States Senate,' page 366

I wish next to refer to Report No 926 of the House of Representatives giving Mr Rankin's report on H R 3749 to the Committee on World War Veterans' Legislation This bill amends the Servicemen s Readjustment Act of 1944 The following quotation from Mr Rankin's report is pertinent to the recommendations made by this subcommittee

"Title II of the act, pertaining to education of veterans would be liberalized by extending the time in which a course can be initiated from two to four years after either the date of discharge or the termination of the present war, whichever is the later, and by extending the period during which education or training may be afforded from seven to nine years after the termination of the present war It will provide for short intensive postgraduate or vocational courses of less than thirty weeks, with a provision that there shall be charged against the veteran's period of eligibility the proportion of an ordinary school year which the cost bears to $500 The rate of subsistence allowance will be changed from $50 to $60 per month if the veteran is without a dependent or dependents and from $75 to $85 per month if he has a dependent or dependents'

I wish to report on a meeting at the Veterans Administration Washington D C, attended by the solicitor of the administrator, Mr Edward E Odom, the director of Vocational Rehabilitation and Education Service Mr H V Stirling, the chief of the Education and Training Division Mr Abbott L Combs, the chief of the Advisement and Guidance Division Mr Ira D Scott, and for the Committee on Postwar Medical Service Dr Victor Johnson, Dr Frederick Coller and myself At this meeting the discussion centered chiefly on the question whether it would be possible to achieve the purposes which we all have in mind that is to secure the recognition of the hospital as an educational institution and of the physician veteran serving a residency as a student, through regulation or a reinterpretation of the regulations or whether, to secure this purpose new legislation is necessary It was agreed that new legislation would not be required and that, if the Administrator of Veterans' Affairs can be assured by the appropriate officials of his own agency that the regulations are sufficiently flexible to include hospitals under educational institutions the committee's purposes could be achieved The further question was raised concerning the amendments to the existing law recommended by the subcommittee Mr Odom assured the Committee that these details were included in the amendments contemplated by the Finance Committee of the Senate, which had held hearings on H R 3749

It was determined finally that on behalf of the subcommittee a letter should be addressed to General Bradley concerning the definition of the hospital as an educational institution for the purpose of Public Law 346 The letter was transmitted to General Bradley under date of November 9 It contains an explanation of the problem and then formulates the problem as follows

"In the light of these facts, we strongly recommend that hospitals conducting acceptable residency programs be considered as educational institutions eligible for tuition benefits under Public Law 346 as amended whether or not the hospital is affiliated with a medical school and provided the hospital demonstrates that the educational program involves a financial outlay by the hospital We also recommend that physician veterans enrolled for such education be considered eligible for subsistence benefits under the law, provided these veterans are otherwise eligible

The letter was answered under date of November 29, 1945 The essential part of the answer is the following

'I am advised by the solicitor and concur in his opinion, that the training contemplated in connection with residencies and fellowships is not "training on the job' within the contemplation of the Servicemen's Readjustment Act but is in the nature of institutional training It therefore is not subject to the prohibition contained in the act against paying institutions for affording "training on the job"

Finally, I wish to report a resolution unanimously adopted by the House of Delegates of the Michigan State Medical Society at its Detroit session It should be noted that the resolution pertains to the tuition payment for refresher courses lasting for shorter periods than thirty weeks Public Law 346 authorizes payment to an amount "which bears the same relation to the maximum amount allowed . . as the length of the course bears to an ordinary school year of thirty weeks" In the amendments Mr Rankin in his report states that H R 3749 "will provide for short intensive postgraduate or vocational courses of less than thirty weeks, with a provision that there shall be charged against the veteran s period of eligibility the proportion of an ordinary school year which the cost bears to $500' The amendment does not in reality touch the problem raised by the Michigan State Medical Society It is recommended therefore, that the resolution of the Michigan State Medical Society should be transmitted with the endorsement of the Committee on Postwar Medical Service to the appropriate agency in Congress when and if it becomes apparent that such transmissal will be effective

After lengthy discussion the report was accepted with thanks as one of progress, and the Chairman announced the appointment of Dr Johnson as an additional member of the subcommittee The Chairman also stated that the subcommittee would continue to have the same authority to investigate and take action as in the past

DEMOBILIZATION OF MEDICAL OFFICERS

Dr Coller chairman of the Subcommittee on Formulation of Lists of Medical Officers to be Considered for Demobilization presented the following report

This is a terminal report This subcommittee was activated last spring even before the end of the war in Europe, and conferences were held with the Surgeon General of the Army and the directing board of the Procurement and Assignment Service at which a method was worked out whereby it was hoped that certain teachers would be released from the armed forces A total of 256 medical officers considered essential teachers by their medical schools were given opportunity to leave the service and resume their teaching positions

ACCELERATION OF DISCHARGE OF MEDICAL OFFICERS

General Lull informed the Committee, and Colonel Piper substantiated his statement, that at least 15,000 physicians would be separated as of Dec 1, 1945, with 15 000 more out of service by March 1, 1946 General Lull and Colonel Piper concurred in the statement that by the 1st of March 1946 about 15,000 physicians will be left in service and about 5,000 ASTP men will be on duty by the 1st of July 1946.

Captain Eaton stated that the essential list of Navy medical officers who are former instructors or teachers in institutions contains 126 names. Of these 66 remain. Thirty-nine of the latter have enough points for discharge and may be out already. We have no means of checking, as this is a field matter and probably disposed of by this time. Twenty-seven of the 66 have not put in for release or otherwise are not accounted for. When these apply they will be discharged. Five of these will have enough points by Jan. 1, 1946. All of 66 could go if they would apply. With regard to those who have enough points to get out and who have not yet been discharged, the difficulty is in getting suitable relief to take the place of the dischargee. Six hundred are on the sick list and 2,500 are in transit, so that the delay is a matter of circumstances.

Originally 60 points were required for discharge. On Nov. 1, 1945 these were lowered to 53 and on January 1 will be lowered to 51, and it is possible that the number will be less than this according to conditions.

RELEASE OF MEDICAL OFFICERS ASSIGNED TO *VETERANS ADMINISTRATION*

Colonel Mella stated that the same criteria apply to the Veterans Administration as apply to the Army of the United States and that, as of Dec. 15, 1945, a large number of A. U. S. officers assigned to the Veterans Administration would be demobilized. He further stated that about 60 per cent of those eligible for discharge asked to stay with the Veterans Administration and of the 40 per cent who desired to leave a great number are trying to call back their requests. He also said that the Veterans Administration was of the opinion that a proportion of the ASTP men should be assigned to the administration. Colonel Piper stated that medical officers now being assigned to the Veterans Administration are those who were formerly on duty with the Administration in a civilian capacity, those who volunteered for such duty and ASTP students, physically disqualified for duty with the Army but physically qualified for duty with the Veterans Administration.

The report of the subcommittee was accepted.

NATIONAL RESEARCH FOUNDATION

The Chairman announced that he had received a letter from Dr. Francis Blake, chairman of the Subcommittee to Study the Bush Report on Proposed National Research Foundation, in which it was stated that the subcommittee had no additions or changes to make in the report submitted to the Committee at the September meeting.

Dr. Austin E. Smith, Secretary of the Council on Pharmacy and Chemistry of the American Medical Association, presented the following statement:

> By now, practically every one recognizes that the federal government is certain to provide funds for research. This is inevitable, although not all are agreed that it is advisable. The doubt that exists in some minds is based on the fear that government subsidy of research may result eventually in the control of research, a fear which, in my mind, is justified unless a sound foundation is laid before the funds are distributed. All of us want to see more and better research. All of us want to see provided, if possible, sufficient funds to make research even better than it has been. All of us want to see such funds allocated in a fair, just and productive manner. None of us, it is certain, want to see research become another political football.
>
> With these thoughts in mind, the Council on Pharmacy and Chemistry has voted approval of the *underlying principle* which motivated the Vannevar Bush report and of the basic principles of the report itself. This committee has already received from the Council office a communication concerning the Bush report. My personal convictions are in harmony with the furtherance of research such as has been visualized by some of our better researchers. They are not entirely in harmony with all who have expressed thoughts on the *foundation* and who have advocated certain proposals for action. It is evident that whatever scheme is adopted will have to be sufficiently flexible to be adjusted as experience is gained. It is evident that there should be fair representation of medicine on the directing board, as on medical research depends much of this country's future economically and otherwise. It is evident that there should be a minimum of confusion when bills are passed, plans laid and activities begun.
>
> For these reasons and others, I would urge that social sciences be not considered, at least at this time, with physical and medical sciences, that the funds and personnel be not handled in such a way as to provide unyielding and inhibitive demands and that the directing forces stem from individuals who can truly visualize the breadth and importance of research. In the same sense I would like to see less argument concerning which *is the best available* bill and more thought concerning what is the best possible bill. So far there has been much discussion centering around the method of *appointing a director and board for the* foundation. The selection is vitally important. It will make or break the project. At this time, based on experience gained elsewhere, it would seem best to keep directorship out of political battlefields.
>
> If it were possible always to regard the whole setup as an experiment that could be changed in toto if experience indicated, there would be less need to worry concerning the actual details of operation. Unfortunately, it is often less difficult to establish something than to abolish it, even when the project eventually proves disappointing. I *myself hope* that the foundation will be even more successful than is expected. Its success, however, will depend on the interest taken by the best men in the country and that interest must be continued, forcefully if necessary, as long as the foundation is in existence.

Dr. Smith then offered *a recommendation that the Committee* on Postwar Medical Service have a subcommittee which will continue to watch all attempts at research under federal auspices, the National Research Foundation and any other research promotions to see if any good is coming from them, whether they are being politically controlled and who is getting the most benefit.

Dr. Smith's statement was received with appreciation.

THE MEDICAL PROFESSION AND MEDICAL EDUCATION IN THE PHILIPPINES

Miss Switzer *reported that she had presented to Commissioner* McNutt the statement adopted by the Committee on Postwar Medical Service at its meeting in September offering its support to any program which he might develop for the use of *surplus supplies or materials to help in the Philippine situation.* Miss Switzer read the following memorandum:

> Dr. Howard Smith and Mr. McNutt are very appreciative of the proffer of the committee on Postwar Medical Service to help in any *way possible in the rebuilding of the Medical School of the University* of the Philippines at Manila. Dr. Smith told me that the dean of the school, Dr. Antonio Sison, attended the meeting of the Association of American Medical Colleges recently held at Pittsburgh and secured the cooperation of *that group. He felt that the organizations* represented on *our committee could perhaps be most helpful by the donation of materials.* Dr. Sison secured a generous offer from the Blackstone Publishing Company to send to the university library copies of their medical books now available. Dr. Smith felt that one of the choicest gifts to the library would be copies of the *Philippine Journal of Science,* since the whole *file of this magazine was destroyed; it is very valuable for* that area. Suggestions as to where copies of that journal may be available would be most helpful, since practically everything in the library was destroyed. Any contributions of files of magazines or reprints will help. The medical society's files were not completely destroyed but will need supplementation.

Dr. Paullin, who, when it was known that he was to go on a mission to the Far East for the U. S. Navy, *had been* requested by the Committee on Postwar Medical Service and the Board of Trustees of the American Medical Association to learn everything possible as to the situation there, presented a comprehensive report, which was received with appreciation. (Dr. Paullin's report was published as a part of the proceedings of the House of Delegates in The Journal, Dec. 22, 1945, p. 1178, under the heading "Much Needed Assistance to the Philippines.")

The Chairman stated that it is planned at the headquarters of the American Medical Association to provide subscriptions to the Association's periodicals and to send other medical literature to the Philippine Medical Association and to the University Medical School and Hospital, that Dr. Peter Bassoe of Chicago only a few days prior to his death had donated his personal library for disposal by the American Medical Association to a deserving cause, and that it was the intention of Dr. West to ship that material to the Philippines as soon as possible.

LICENSURE OF RETURNING MEDICAL OFFICERS

Dr. Bierring presented the following report, which supplements the report submitted by him at the meeting of the Committee in September:

> 1. Admission to licensure by state medical boards of graduates of unapproved medical schools who have demonstrated their competence in connection with their military service: As stated in the previous report, Illinois and Massachusetts admit to licensure graduates from unapproved medical schools located *in their respective states.*
>
> At a meeting of the Massachusetts Board of Registration in Medicine Nov. 17, 1945 the following policy was adopted:
>
> "Graduates of unapproved medical schools who have demonstrated their competence in connection with their military service would be obliged to take our *regular examination and would* be graded 10 points for their military service."
>
> It would appear from this action that the Massachusetts Board is admitting to examination graduates from unapproved medical colleges located in other states.

In the first report the special provision for hospital graduates in New York State was stated as follows:

"The Veterans Committee will pass on all such applications, and if they can show one or two years of military service during which time they have been actively engaged in medical or surgical work the board will endeavor to admit them to the licensing examination. If they have not had active medical or surgical work while in the armed forces, one year of attendance at an approved medical school will be accepted,"
and this evidently still prevails.

There is no change regarding this problem in any of the other states.

2. Licensure requirement for hospital residencies: As stated in the first report, the following states and the District of Columbia require a license from a hospital resident: California, District of Columbia, Illinois, Indiana, Kansas, Michigan, Minnesota, Nevada, Ohio, Oklahoma, South Carolina and Wisconsin require a license from a hospital resident.

Nebraska and Texas require a license if the resident engages in independent practice.

Rhode Island requires a license after one year of residency.

New Jersey requires a license after two years of residency.

Puerto Rico requires a license for resident, but the license is granted without examination.

Since the last meeting of the committee an effort has been made to have state boards consider hospital residencies as a part of postgraduate training, particularly as it applies to the returning medical officer.

Replies have been received on that question from the following states:

California: State law still requires licensure for hospital residencies. No provision is made for army or navy medical officers under any conditions. Must secure license under the existing laws.

District of Columbia: If returning medical officers perform duties of interns only no license required. If they diagnosed and/or treated on own responsibility, license required. Local medical practice act contains very broad definition of practice and requires all who practice locally to have District of Columbia license.

Illinois: Rules of this department have not been amended to exempt medical officers from licensure requirement during residency except as to the completion of the first three months' service which may be required to complete twelve months' hospital work required by Illinois law.

Indiana: No change in present regulations.

Kansas: No change.

Louisiana: Residencies in private hospitals must have license. The Charity Hospitals in New Orleans and Shreveport are exempted.

Michigan: Previously we have sent you the opinion of our attorney general in that the Michigan State Board of Registration in Medicine has no authority to exempt from Michigan medical licensure other than the internship period which the board is authorized to fix, completion of which Michigan medical licensure is essential.

Minnesota, Nevada, Oklahoma, South Carolina and Wisconsin: No change.

Ohio. Dr. Herbert M. Platter, secretary, Ohio State Medical Boards: "Believe matter could be handled under supervision of the staff.

Massachusetts: At a recent meeting adopted the following policy regarding returning medical officers for hospital residencies in the specialties: "There is no examination for this type of license. The applicant furnishes the board with proof that he is 21 years old, is of good moral character, has completed creditably not less than three and a half years of study in medical school and has received an appointment as an intern or resident or fellow in a hospital conducted by commonwealth, county, city or incorporated under laws of the state. Fee for such registration is $5, issued for one year and may be extended for not more than three years. Such registration limits work of resident, fellow or intern to the four walls of the hospital where he has his appointment."

It seems evident that, aside from the several exceptions noted, the state medical boards require state licensure for hospital residencies and are not inclined to accord special consideration to returning medical officers and to exempt them from state licensure in accepting hospital residencies as a part of postgraduate training.

At the meeting of the council of the Association of American Medical Colleges in Pittsburgh, October 29 and 30, the following resolutions were adopted:

"Whereas, The hospital residency is generally recognized to be an essential education experience in the various special fields of medicine; and

"Whereas, The hospital residency is required by the several specialty boards as prerequisite for admission to examination by those boards; be it

"*Resolved*, That the Association of American Medical Colleges requests the Federation of State Medical Boards to effect such changes in their respective state laws or regulations as will permit graduates in medicine to pursue such educational opportunities as are approved by the specialty boards, the Council on Medical Education and Hospitals of the American Medical Association and their respective boards without formal licensure to practice medicine during this period of training."

This resolution and other matters pertaining to licensure problems affecting the returning medical officer will be considered at a meeting of the executive committee, Federation of State Medical Boards, on Dec. 3 and 4, 1945.

Subsequent developments in the foregoing problems will be reported at the next meeting of the Committee on Postwar Medical Service.

The report submitted by Dr. Bierring was accepted.

REPORT TO HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION

The report of the Committee on Postwar Medical Service to the House of Delegates of the American Medical Association, prepared by the Chairman, was presented and was approved by the Committee. This report was published as a part of the proceedings of the House of Delegates in The Journal, Dec. 22, 1945, page 1185.

MOTION REGARDING SURPLUS MEDICAL AND DENTAL SUPPLIES

A motion offered by Dr. Camalier, recommending that there be a more liberal interpretation of the present surplus property law or changes in the regulations or a change in the Surplus Property Act in order that returning medical and dental officers might obtain needed material more promptly, failed of adoption.

In view of the importance of the dental portion of the surplus property problem, the Chairman, with the approval of the Committee, appointed Dr. Camalier as an additional member of the Subcommittee on Surplus Medical and Hospital Supplies.

TIME AND PLACE OF NEXT MEETING

It was decided that the next meeting of the Committee would be held at American Medical Association Headquarters at 10 a. m., Jan. 12, 1946.

The meeting adjourned at 1:20 p. m.

Council on Medical Service and Public Relations

IOWANS OPPOSE COMPULSORY HEALTH INSURANCE

The Iowa Poll revealed in its first survey on the compulsory health insurance issue that Iowans oppose President Truman's plan. According to a news release in the Des Moines *Register*, Dec. 16, 1945, "among those who would like to have Congress enact the president's recommendation into a law, about one in four would not be willing to pay 4 per cent of income to have the plan."

The question asked was as follows: "President Truman recommends that Congress pass a law setting up compulsory health insurance. Under his plan, sickness expenses such as doctor bills, hospital bills and dentist bills would be paid by the government out of a new tax on people's earnings. Do you think Congress should pass such a law?"

The resulting answers showed:

	Total	Men	Women
Yes	40%	42%	39%
No	49%	51%	48%
No opinion	11%	7%	13%

U. S. DEATH RATE UNDER PREWAR

The recent monthly press release by the Institute of Life Insurance pays tribute "to the care the American people have taken in the face of wartime work pressure and the acute shortage of doctors." The report shows that the death rate among civilian owners of life insurance policies may prove to be the lowest on record except for 1942.

The release reports the following:

Heart disease continued in the lead as the major cause of death, accounting for 30 per cent of civilian policyholder deaths, although the rate was not much changed from that of 1944. The current death rate from diseases of the heart and arteries is 6 per cent above that for prewar 1941. Cancer, second in importance, accounted for 15 per cent of civilian deaths and showed an increase over both 1944 and 1941.

Offsetting the increase in deaths from heart disease and cancer, there have been improvements in other directions, with sharp reductions in some cases. Deaths from the major children's diseases have dropped materially from last year and are about one third below prewar. The tuberculosis death rate is 7 per cent under 1944 and 12 per cent under 1941, contrary to past wartime trends. The death rate for influenza and pneumonia this year is nearly one third below last year and 1940, although an epidemic of respiratory cases, not yet serious, was reported at the end of the year.

One especially disconcerting change of the year is that involving automobile accidents, the death rate from which has sharply increased since lifting of gasoline rationing.

THE STATUS OF THE ENGLISH DOCTOR

(The following article was submitted by Capt. Paul K. Maloney, M. C., A. U. S., a member of the Kings County Medical Society in New York, to the Bulletin of that medical society. It is here reprinted for the general information of American physicians as to the present technic of operation of the panel system in Great Britain.—Ed.)

This material was obtained from one of the general practitioners in Kidderminster, a city with a prewar population of 30,000 which has now risen to 60,000. He is a man who has practiced "panel medicine" for ten years and has made a success of it, as far as that is possible. He has answered all questions frankly and analytically without trying to cover up the defects of the system.

This article will deal only with the practical aspects of the doctor-patient relationship and with the financial status of the doctor, rather than with the complicated and extensive administrative machinery that has come into existence. The object here is to outline how the average British citizen obtains medical care for himself and his family. For that reason the information is presented in three parts:

I. The machinery to provide the wage earner with ordinary general practitioner's care. This is called National Health Insurance and is regulated by law.

II. The machinery to provide the same thing for his dependents. This is a private venture, undertaken by a group of doctors who organize a "public medical society" for the purpose. Financial arrangements vary somewhat according to the charter of this society.

III. The machinery to provide consultant's services and hospitalization for both the wage earner and his family. This is undertaken by the "voluntary hospitals," which are run by the city or county and supported partly by private donations and partly by small subscriptions from those who wish to have a hospital insurance.

I. National Health Insurance

National Health Insurance has existed in England since about 1911, when it was passed under the sponsorship of the then Premier Lloyd George. At first it met with much opposition from the medical profession, and there were many doctors who refused to take on a panel. Wherever the system threatened to fail because of this, the government placed young medical graduates in the recalcitrant locality. This was not difficult, because in England a doctor must buy a practice when he starts and there were plenty of young men who here saw a chance to acquire a practice (even though it was only a panel practice) without having to pay the usual sum of £3,000 to £10,000 for it. Since then, health insurance has been accepted by the vast majority of doctors as an inevitable institution. In Kidderminster, of a total of thirteen doctors eleven practice panel medicine.

National Health Insurance will be discussed under the following headings:

1. What people are insured.
2. What service is provided.
3. Financial arrangements.
4. The "Approved Society."
5. The status of the doctor (*a*) financially, (*b*) professionally.

1. *What People Are Insured.*—The scheme includes every wage earner, male or female, married or single, between the ages of 14 and 64, with an income of less than £420 a year (until the war this figure was £250). The fees are deducted automatically from the pay check, so that the system may be said to be compulsory.

When the wage earner is temporarily unemployed, the state continues the payments for him, *provided he is on the dole.*

When the wage earner reaches the age of 64 he stops paying all fees, becomes entitled to the old age pension and remains insured for the rest of his life.

When he stops paying before the age of 64 (this would be impossible with people getting regular pay checks, because the deductions are automatic) he remains insured for two years after his delinquency.

People whose income is not paid in the form of a wage, such as shopkeepers, farmers and small pensioners, may make their payments quarterly. They do come within the provisions of the law, as long as their income is less than £420.

The £420 limit means that well over 90 per cent of the population of England is included.

2. *What Service Is Provided.*—This includes ordinary physician's care, office as well as house calls. No surgery except the most pedestrian kind, such as lancing a boil. The scheme also allows for some drugs, but only the less expensive ones. For those who belong to an "Approved Society" it is sometimes possible to get spectacles and dental and surgical appliances free of charge.

3. *Financial Arrangements.*—Payments are made by the week or month. They are divided equally between the employee and the employer, with the employer paying the odd penny if there is one. The total weekly contribution for individuals of 18 and over is 1 shilling 7 pence (1/7), of which the employer pays 10 and the employee 9. For an additional 3 pence (/3) it is possible to secure a very small "sickness benefit," that is an allowance during illness, but it does not amount to more than 10/ a week and only for a limited time. The /3 is paid by the employee. Shopkeepers, farmers and pensioners pay 1/5 a week, all themselves. The money is collected automatically by pay check deduction and a 1/7 stamp is pasted in a special card that is provided for this purpose. The stamps are bought at the post office.

Thus, the fund collects fifty-two times 1/7, or about 82/ a year. This is apportioned as follows:

For the doctor, 10/6, or 12.5 per cent
For drugs, 3/, or 3.5 per cent.
For mileage fees at the rate of a shilling per mile per year, /6, or 0.5 per cent.
For administrative overhead, 68/, or 84.0 per cent.

Attention is called to the disproportion of what the doctor gets and what the state collects. Up until 1939, the Fund had accumulated a surplus of £144,000,000.

4. *The "Approved Society."*—This is a sort of private insurance company, organized to help administer the scheme and give certain extra advantages to the "good risks." Only those wage earners who make separate application and who can pass a physical examination are accepted (the National Health Insurance Act itself makes no mention of a physical). The chief object of the approved society is to provide "sickness benefits," that is, small weekly payments to those who are ill and cut off from their regular source of income. It has already been pointed out that for an additional /3 a week the insured person may get a government sickness benefit, but the payments are small (not more than 10/ a week) and last only as long as there is a cash balance in his particular account. The approved society, on the other hand, is authorized to collect 4/10 out of the 82 shillings that is taken in for each individual who is a member. For this it gives:

(*a*) A sickness benefit of from 18/ to 25/ a week, which is paid as long as the illness lasts. The variation of 18 to 25 depends on the society. The better ones pay the larger amount.

(*b*) "Grants-in-aid," that is, spectacles, dental appliances and surgical appliances, but only in limited amounts. A certain sum is set aside at the beginning of each year and, when this is exhausted, no further grants can be made until the next year. Usually, the fund is used up long before the year is out.

The people who cannot belong to an approved society because of some disqualifying physical defect such as hypertension or diabetes are called deposit contributors. It is optional with them if they want to belong and pay the extra /3 a week.

5. *The Status of the Doctor.*—(*a*) Financially. A successful, busy practitioner can handle a panel of 2,000. The upper limit, fixed by law, is 2,500. A panel of 2,000 yields a yearly income

of somewhat over £1,000. This may be increased slightly by the "certificates of disability" which the doctor writes for those whose illness compels them to stay away from work. Such a certificate costs the patient 1 shilling. Since 95 per cent of the cases are ambulatory, the profits on this score are small.

In Kidderminster, with a panel of 2,000, the doctor sees an average of 30 patients a day, or 9,000 a year, so that his pay per office or house call is 2 shillings.

(*b*) *Professionally.* Professionally, the doctor's position is not a happy one for the following reasons:

Inspectors come around regularly to inspect his records. If these fail to pass, the doctor is fined without further process of law anything from £100 to £200. If a patient is disgruntled, he can report the doctor, and the doctor is then investigated by a board, made up partly of laymen, partly of doctors. Again, the penalty is in the form of a fine, although this sort of trouble is usually squelched before it reaches a board. The fact remains, however, that a crackpot patient can cause the doctors no end of unpleasantness.

More irritating is the limitation in the allowance for drugs. Only certain inexpensive items may be prescribed. When two doctors in London, unaware of this, ran a large-scale scientific experiment on their aged patients by giving them large doses of cod liver oil and malt extract (the doctors acted in good faith and accumulated valuable data), they were fined £1,000. This raised such a furor that the affair was investigated in Parliament. Regretfully, Parliament had to agree with the verdict because it was within the purlieus of the law.

Further, there is the limitation of what the doctor may do for his patient. The law says he may do only what is commonly considered to be within the province of the general practitioner. This definition has been tested repeatedly in court and has been very narrowly interpreted. For instance, a doctor may not inject hemorrhoids, give diathermy, remove polyps or electrocoagulate warts. In fact, about the only thing he can do is to prescribe some inferior drug and he resorts to that abundantly. If the patient needs a consultant or an operation, he must be sent to the hospital. The practitioner then loses track of his patient altogether, but a few with special training may apply for staff privileges. In Kidderminster, out of a total of thirteen physicians, there are only two who may operate. These are paid a small fee when they operate on a panel patient. An appendectomy nets them £1.

The average office call for a panel patient lasts three minutes: one minute to usher the patient in and out, one minute for the questioning and examination, and one minute for the writing of the prescription and the records. Since the doctor also sees many "club patients," his average daily quota of patients is from 60 to 70, about three quarters office work and one quarter house calls. His day lasts from 9 in the morning till 8 in the evening. He takes one afternoon a week off, plus his Sunday, and a two to three weeks vacation every year.

II. The Public Medical Society

To provide the wage earner's dependents with this same sort of care, doctors organize locally what is called a Public Medical Society, or "club." They hire an accountant, collectors and typists for the bookkeeping and take on a certain number of people on a sort of private panel. The average number per doctor is 1,000. The cost is 4 pence a week per individual up to a maximum of 1/4 for a single family. After that there is no further increase, so that very large families are not unduly penalized. The distribution of the profits is very interesting when compared with those of the National Health Insurance. It is as follows:

For the accountant, 7.5 per cent.
For the collectors, 12.5 per cent.
For the doctors, 80.0 per cent.

The main lesson to be learned here is that, when the state operates the system, the doctors get 12.5 per cent, but when the doctors themselves operate the system they get 80 per cent!

By having 1,000 "club patients," a practitioner can further increase his income about £660 a year. The subscribers are, of course, mainly women and children. Although they represent only half the size of the regular panel, they account for fully as many office calls, an average of thirty a day. Add to this 30 panel patients and the total becomes 60. A very ambitious man such as the one interviewed also sees about 10 private patients a day, who add some £400 to £500 a year to his income. Consequently his total income is about £2,000 a year, which is not bad even at home, but it must be remembered that he is now at the top of the heap as far as panel practice is concerned.

III. The Voluntary Hospital Contributory Scheme

To provide hospital care for the wage earner and his family there is still another scheme. It is operated by the hospitals themselves, as far as they wish to, and most of them do. A voluntary hospital exists from two sources, each one of about equal size: (1) private donations and charity drives; (2) small subscriptions by individual workers.

The fee for one wage earner and his family is 4 pence a week, to which the employer adds 1 penny, making a total of 5. There is no compulsion about it as there is about National Health Insurance. The 5 pence a week yields 21/4 a year. The Kidderminster Hospital collected £18,000 this way last year, about half its total operating cost. By being a "voluntary contributor," the wage earner insures hospitalization for himself and his family for no matter what ailment or what operation, chronics excepted.

The hospital in Kidderminster has a staff with one specialist for each of the important departments, such as surgery, medicine, x-ray and laboratory. None of these get paid, except for the surgeon, who gets £100 a year for being the head of the outpatient department. The radiologist gets no salary but has the privilege of using the department for his private patients. Consultants who must come from distant cities get a mileage fee of £100 a year.

Obstetrics, which is usually a large source of income for the general practitioner at home, is not so in England because 95 per cent of the work on indigent patients is done by midwives. Doctors are called in only when there are complications. The scheme is administered by the county, which pays the doctor 2/6 for each antepartum office call and 5/ for a house call. If the doctor does the delivery himself he collects 3 guineas and his anesthetist 1 guinea. This is paid by the county after an investigator has certified that the patient cannot pay. If the patient can pay something the doctor gets a corresponding fraction of his 3 guineas. Even in the very active practice of our informant, however, obstetrics played only a minor part.

Disadvantages of Socialized Medicine in England

The chief disadvantages of panel practice appear to be from this superficial survey:

1. The impossibility of doing good work because of the volume of work.
2. The restrictions on what the doctor can do for his patient in the office.
3. The discrepancy between the 10/6 for the doctor and the 68/ for the overhead.

NOTE.—For readers in the United States the shilling is worth about 20 cents and is written with a / sign. Thus, 5 shillings 4 pence is written 5/4. There are 12 pence to the shilling and 20 shillings to the pound.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Feb. 11-12. Dr. Victor Johnson, 535 North Dearborn St., Chicago, Secretary.

Conference of State Secretaries and Editors, Chicago, Feb. 8-9. Dr. Olin West, 535 North Dearborn St., Chicago, Secretary.

American Association of Pathologists and Bacteriologists, Chicago, March 8-9. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.

American Orthopsychiatric Association, New York, Feb. 14-16. Dr. Nina Ridenour, 1790 Broadway, Room 916, New York 19, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 5-8. Dr. Warren W. Furey, 30 North Michigan Ave., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 18-21. Dr. John G. Young, 1719 Pacific Avenue, Dallas 1, Director of Clinics.

Federation of American Societies for Experimental Biology, Atlantic City, March 11-15. Dr. D. R. Hooker, 19 West Chase Street, Baltimore 1, Secretary.

Southeastern Surgical Congress, Memphis, Tenn., March 11-13. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta 3, Georgia, Secretary.

MATERNAL AND CHILD HEALTH SERVICES

Report of Annual Meeting [1] of the Children's Bureau Advisory Committees on Maternal and Child Health Services and on Services for Crippled Children. Children's Bureau, U. S. Department of Labor, Nov. 8 and 9, 1945.

The meeting was called by the Associate Chief of the Children's Bureau particularly to obtain advice on Senate Bill 1318 (H. R. 3922, H. R. 3994, H. R. 4059) known as the "Maternal and Child Welfare Act of 1945." To this end six committees were appointed from the members of the advisory committees to consider on November 8 various aspects of the proposed legislation and report their opinions to the general session of the committees on November 9.

The reports as modified and accepted or adopted in the general session and a statement by Dr. Eliot are transmitted herewith in accord with the unanimous recommendation of the general session in order to make them available for such use as each member of the Advisory Committees and the Children's Bureau might deem desirable.

* * * * * *

Report of Committee to Consider Basic Philosophy and Principles Pertaining to S. 1318

This committee discussed many fundamental principles pertaining to such legislation as proposed in S. 1318.

Certain reservations as regards the jurisdiction of the federal administrative agency under this bill, its departmental allocation and the integration of this agency, and the proposed maternal, infant and child medical care program with other federal health plans were discussed. Before giving critical consideration to the details of the proposed legislation the Committee wishes to make it clear that such consideration does not necessarily constitute an endorsement of the proposed allocation to a bureau in the Department of Labor of authority to develop and direct such an extensive medical care program.

The Committee recognizes the far reaching and significant contributions of the Children's Bureau to maternal and child health, especially in the fostering of high standards of medical and welfare services. However, in such a program as envisaged in this major step in the development of a federal health program problems of state's responsibilities and relationships with federal agencies are involved which demand consideration of the qualifications of the proposed agency for their conduct and consideration of ability to integrate the proposed program with those for the provision of health and medical services for the remainder of the population.

The Committee recommends that Congress give careful study to the problem of the proper agency to conduct this program and of the relationship between governmental agencies concerned with medical and health services.

Disapproval of paragraph (3), page 4, line 3 of section 103 was voted by 10 members, while 6 members voted approval.

The following modification (italicized) of paragraph (3), page 4, line 3 of section 103 was favored by 14 members and opposed by 3 members:

> (3) provide that as services and facilities are furnished under the plan they shall be available to all mothers and children in the state or locality *who are determined by the state health agency to be eligible and* [2] who elect to participate in the benefits of the program, and that there will be no discrimination because of race, creed, color or national origin, and no residence requirements;

Among the 14 who favored this modification were members who were opposed to the means test in principle but felt that the modification was essential to a tolerant consideration of such legislation at the present time.

It was also felt by some that if the application of a means test was left to each state the ultimate development through the nation of efficient plans for medical care, such as considered here, would not be jeopardized.

It was felt by others that this was a wholesome endorsement of state rights under such a program.

There was lengthy debate on the means of protecting medical education and through it the quality of medical care if such legislation as proposed in S. 1318 should be enacted. The Committee was in general agreement that careful consideration of the effect of such legislation on medical education and the quality of future medical care was essential if both were to be protected. Though no formal vote was taken, the Committee felt that perpetuation of medical indigence was not a prerequisite to good medical teaching and better medical care.

While no formal expression of opinion was expressed, it was pointed out that provision for the remuneration at the same rate whether the professional services were rendered by groups of professional personnel, including teaching units, or by individuals was desirable in terms both of protecting the quality of teaching service and of protecting the interests of individual physicians or other professional personnel.

Designation of members of the advisory committees of the Children's Bureau as individuals representing no organization or as the official representative of an organization was suggested. It was furthermore urged that a member who was designated as the official representative of an organization be given the power of negotiating for that organization.

In the general session November 9 this report was adopted unanimously.

Statement by Dr. Martha M. Eliot [3]

The policies of the Children's Bureau in its administration of the Emergency Maternity and Infant Care program have been referred to a number of times today and yesterday as possibly setting precedents that would not be desirable under a longtime program of services to mothers and children.

The Emergency Maternity and Infant Care program was satisfactory only as an emergency program. The Children's Bureau recognizes that, in the development of a longtime program, administrative authority of the federal and state agencies must be clarified and definitely placed. I believe that a longtime program should be state administered. I believe that under the Emergency Maternity and Infant Care program more responsibility and initiative had to be taken by the federal agency because of the emergency than would be desirable under a longtime program.

I would like to point out that S. 1318 is not an extension of the Emergency Maternity and Infant Care program for the following reasons:

1. The bill provides for an evolutionary development of the maternal and child health and crippled children's programs, state by state, over a ten year period on the basis of local and state needs and resources for meeting these needs.

2. The bill gives to the states the initiative for development of and the responsibility for carrying out state policies and procedures necessary for the operation of the state plan. The role of the federal agency would be to establish policies related to minimum standards for care and appropriate use of federal funds to carry out the purposes of the legislation.

3. This bill makes provision on a legislative basis for methods of maintaining and improving quality of care, which, under the Emergency Maternity and Infant Care program, had to be left to the Children's Bureau because of the emergency nature of that program.

---

[1] Condensed from the report prepared by Dr. Alan C. Butler at the direction of the Advisory Committee.

[2] The modification is indicated by the italicized portion.

[3] Statement made by Dr. Eliot, Associate Chief, Children's Bureau, U. S. Department of Labor, at general session, Nov. 9, 1945, of Children's Bureau Advisory Committee on Maternal and Child Health Services and Advisory Committee on Services for Crippled Children and by direction of the Advisory Committees to be attached to the Report of the Committee to Consider Basic Philosophy.

4. The bill requires the Children's Bureau to obtain the advice of federal advisory committees, both general and technical, and of the state administrators concerned, before establishing federal policies to be used as guides in approving state plans. Furthermore, the bill provides for the same type of cooperation between the state administrative officials and the professional and public groups concerned.

The question of maximum fees to be paid from federal funds would, of course, have to be discussed and studied by the bureau with the professional and governmental groups concerned.

The Children's Bureau believes that the program proposed under this bill (S. 1318) would be one essential segment of a national health program and that it can and must be fitted into an overall medical care program when such is developed.

I would like to say further for Miss Lenroot and myself that we would have no objection to the transfer to another department with cabinet rank under conditions that would safeguard the integrity of the Children's Bureau and the services included in the Children's Bureau program. I would like to say further that Miss Lenroot and I would consider transfer of the Children's Bureau to an independent agency without cabinet rank as a great sacrifice for the bureau.

Majority Report of Committee on Availability of Services and Facilities

The meeting was opened by the Chairman reading subsection (3) of section 103, title I, of S. 1318, the "Maternal and Child Welfare Act of 1945":

> (3) provide that as services and facilities are furnished under the plan they shall be available to all mothers and children in the state or locality who elect to participate in the benefits of the program, and that there will be no discrimination because of race, creed, color, or national origin, and no residence requirements;

A number of the medical members present felt that the bill was unacceptable to the medical profession without the inclusion of a means test. To these the provision of services of this kind at public expense seemed an undesirable lessening of individual responsibility. Any means test would have to be conducted on a local level and administrative expenditures varying from 35 cents to 60 cents to 80 cents per family would be necessary to carry out such a test, and probably in the groups close to the upper limit it might have to be repeated every six months.

Those in favor of the subsection, as read, felt that health, like education, was something to which every American child and mother during pregnancy and the postpartum period were entitled. That in view of the fact that 85 per cent of the families had an income of less than $2,500 per year, and 92 per cent less than $3,000, there would be no great group of children that would be getting this service undeservedly.

After a considerable discussion, the matter was finally brought to a vote. The motion was made "That the means test should be used in the administration of the Pepper Act." The vote was 5 for the motion and 8 against the motion.

In view of the fact that there was considerable opposition to the motion, the Chairman suggested to the minority that it hand in a minority report (which follows):

Minority Report

The minority group of the Committee on Availability of Services and Facilities dissents from the report of the majority on the issue of providing a means test to determine eligibility of individuals or families for participation in the services provided under proposed bill S. 1318. The minority believes that to offer medical service to all, regardless of economic status, in any population group, is an unwise procedure because:

1. It encourages excessive dependence on government and discourages individual self reliance.
2. It tends to congest services intended primarily for the underprivileged and thus to deprive them of full benefits.
3. It places a needless and undesirable burden on taxpayers, especially small taxpayers least able to bear it.
4. It competes unfairly with and tends to discourage established private and semiprivate agencies already rendering meritorious service.

The minority believes in a suitable means test, to be determined at state levels after consultation with appropriate official and social service agencies and medical societies, applicable to medical care aspects only and exclusive of established public health procedures and diagnostic services in preventive medicine.

Reports were received from committees dealing with Methods of Remuneration for Professional Services, on Scope and Extension of Services, on Research Projects and Methods of Establishing Standards of Care, and on Professional Education and Training.[4]

Medical Legislation

STATE LEGISLATION

California

Bills Introduced.—A. C. R. 6-X proposes a concurrent resolution to the effect that, when legislation is enacted to provide for a medical school and center at the University of California at Los Angeles, the Board of Regents of the University of California is urged to select for the location of the medical school and center a site within the area adjacent to the intersection of Vermont Avenue with Sunset Boulevard in said city.

A. 35-X proposes to authorize the appropriation to the Regents of the University of California of the sum of seven million dollars for the purpose of establishing, equipping and maintaining a medical school and center as a unit in the University of California at Los Angeles.

A. 37-X, to amend the business and professions code, proposes to increase the annual tax and registration fees of osteopaths from $5 to $10 for residents and from $2 to $10 for nonresidents.

A. 61-X proposes an appropriation of four million dollars to the Regents of the University of California for the purpose of additional construction, improvements and equipment for the Medical Center of the University of California at San Francisco.

S. 3-X proposes the acquisition of land and buildings for temporary state hospital facilities, such property to be operated by the Department of Mental Hygiene on a temporary basis as temporary state mental institutions.

Massachusetts

Bills Introduced.—S. 118, to amend the medical practice act, proposes that the laws relative to the eligibility of an applicant for registration as a qualified physician in force immediately prior to Jan. 1, 1941 shall continue to govern as to the eligibility of any applicant who shall have received the degree of doctor of medicine prior to the effective date of this proposal from an educational institution legally chartered by the commonwealth of Massachusetts having power to confer degrees in medicine.

H. 232, to amend the law relating to commitments of insane persons, proposes that such commitments shall be made only on the certification of two properly qualified physicians who have been selected by the judge having authority to commit, such physicians having been selected from lists prepared monthly by the judge.

H. 337 proposes the construction of an addition to the Westfield state sanatorium for the care and treatment of persons suffering from cancer.

H. 458 proposes that a veteran eligible for admission to the state Soldiers' Home may be hospitalized and treated at any public or private hospital when there are not sufficient facilities at the Soldiers' Home to care for such veteran. The cost of such hospitalization and treatment shall be paid by the state.

S. 27, to amend the law relating to divorce, proposes to authorize a decree of divorce where both parties are residents of the commonwealth and one of them has become incurably insane and has been confined for at least five consecutive years prior to the filing of the bill for divorce.

S. 90 proposes the enactment of a cash sickness compensation act.

S. 188, to amend the medical practice act, proposes to require every qualified physician to submit annually to an examination and test for venereal disease and to display prominently in his office a certificate of the board stating the date and result of the last examination.

---

[4] This is a condensed report. Inquiries for further information should be addressed to the United States Department of Labor, Children's Bureau, Washington 25, D. C.

Missouri

Bill Introduced.—S. 349 proposes the creation and establishment of a department of public health and welfare.

New York

Bills Introduced.—S. 97, to amend the law relating to animal experimentation, proposes to prohibit experiments or investigations on living dogs, even though performed under the authority of a medical college or university of the state.

S. 119 and S. 124, to amend the education law, propose to establish within the department of education a medical college to be known as New York State Victory Medical College, equipped to provide instruction for four thousand pupils.

Rhode Island

Bills Introduced.—H. 569, to amend the law relating to discrimination by any state department against certain professional groups of the healing arts, proposes to include chiropractors within the group against which no discrimination is allowed.

H. 575 proposes the creation of a special committee to study the several problems arising out of the administration of the cash sickness compensation act and to make recommendations for amendments thereto.

South Carolina

Bills Enacted.—S. 49, approved Jan. 10, 1946, has become Act No. 383, Laws 1946. It provides for the establishment of nonprofit corporations to operate hospital service plans whereby such corporations undertake to pay for hospital care rendered by hospitals to subscribers to such plans.

Washington Letter

(From a Special Correspondent)

Jan. 21, 1946.

Use of DDT Barred in Municipal Buildings

Although Washington is continuing its drive to rid itself of rats and its reputation as one of the most rodent infested spots in the nation, the District of Columbia government has turned thumbs down on the use of DDT as an insecticide in municipal buildings. The District health officer is working out an educational program with respect to the safe use of DDT as a fortifying agent for an insecticide. However, DDT dusting is continuing in a fifteen block area near the 200 block of K Street N.E., where typhus infested rats were found. The Metropolitan View Citizens Association in a letter to the House District Committee, the Senate District Committee, the District Commissioners and the Federation of Citizens Associations, meantime, has called for an investigation of the District Health Department. The association asks for an inquiry regarding delayed ambulance service to municipal hospitals, closing of tuberculosis wards while persons suffering from tuberculosis are not hospitalized, and alleged failure of health inspectors to take "prompt and effective" action against food purveyors whose establishments have been found insanitary.

Army Assigns 5,000 Medical Trainees to Special Duty

The War Department has announced that it will assign to duty with troops more than 5,000 young medical officers who have been studying at government expense in the Army Specialized Training Program. They entered the army as enlisted men and were placed in training which is now being completed through internships and residencies in civilian hospitals after graduation from medical schools. Surgeon General Kirk said that civilian hospitals have been informed so that they may obtain replacements.

Antivivisection Bills Presented in New York and Washington

Efforts to obtain passage of the Lemke bill to prohibit animal experimentation in the District of Columbia will be pressed during the present session of Congress. And from Albany it is reported that the bill to outlaw all medical experiments on living dogs was introduced in the New York State Senate by Senator Richard A. DiCostanzo, Republican of New York, and in the lower house by Assemblyman Irwin D. Davidson, Democrat of New York. A petition claimed to carry more than 119,000 signatures was presented to Governor Dewey in support of the DiCostanzo-Davidson bill. One New York newspaper (the *Journal-American*) has been aggressive in promoting the New York State antivivisection legislation, and similar material has been given prominence in a Washington newspaper (the *Times-Herald*). Early hearings on the District bill have been promised.

American Chemical Society Awards $210,000 for Fellowships

Fellowships totaling $210,000 will be awarded in 1946 and 1947 by the American Chemical Society to aid in training chemists and chemical engineers. President Bradley Dewey said that "predoctoral" students whose work was interrupted by the war will get $100,000. The remainder will go to holders of doctor's degrees who desire one or two years in research and teaching.

Hospital Sets Up Its Own Blood Bank

Since national appeals for blood donations have fallen off with the end of the war, Doctors Hospital in Washington has organized a blood bank to serve its patients on a nonprofit basis. The bank is an affiliate of the Community Blood Plasma Bank at George Washington University. Immediate donations are being sought to get the hospital bank in operation, and persons with type 4 and type O blood have been urged especially to donate now.

Date Set for Highway Safety Conference

Dates for the conference called by President Truman to try to reduce the mounting toll of deaths and injuries resulting from traffic accidents have been set as May 8 to 10 in Washington. The dates were chosen after the President conferred with several organizations promoting highway safety. Major Gen. Philip B. Fleming, federal works administrator, will preside, and Commissioner Thomas H. MacDonald of the Public Roads Administration will be conference director.

Injuries Cost Government $12,000,000 a Year

Injuries to government workers cost the government more than $12,000,000 a year, it was revealed at the recent conference of the Federal Interdepartmental Safety Council. A survey will be made immediately on existing safety work. First items to be examined will be agency accident rates and workmen's compensation claims. Programs of agencies with best records will be given special study.

Official Notes

THE SAN FRANCISCO SESSION

Special Exhibits on Fractures and on Physical Medicine; Section Exhibits for General Practitioner

The Board of Trustees has authorized two special exhibits for the Scientific Exhibit at the San Francisco session, July 1 to 5.

The special exhibit on fractures will be presented again under a committee composed of Dr. Kellogg Speed, chairman, Chicago; Dr. Frank D. Dickson, Kansas City, Mo., and Dr. Walter Estell Lee, Philadelphia. Demonstrations will be continuous throughout the week.

The special exhibit on physical medicine will include physical therapy, occupational therapy and rehabilitation. The demonstrations will be supplemented by motion pictures in an adjoining area. The committee in charge is composed of Dr. Frank H. Krusen, chairman, Rochester, Minn.; Dr. Winfred Overholser, Washington, D. C., and Dr. Howard A. Rusk, New York.

The seventeen sections of the Scientific Assembly will have groups of exhibits dealing with the various specialties of medicine. All exhibits will be presented for the physician in general practice rather than the specialist, however. Application blanks for space may be obtained from the Director, Scientific Exhibit, 535 North Dearborn Street, Chicago 10.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

COLORADO

Personal.—Dr. Walter F. Peer, Brighton, has been appointed a member of the state board of public welfare, succeeding the late Dr. Arthur T. Monismith, Fort Lupton.

State Society Plans Jubilee Session.—The Colorado State Medical Society plans to hold its seventy-fifth annual session in Estes Park, September 11-14, with headquarters in the Stanley Hotel. A special program will commemorate the diamond jubilee of the medical society.

The Maurice H. Rees Scholarship Fund.—To perpetuate the memory of Dr. Maurice H. Rees, for many years dean of the University of Colorado School of Medicine, the board of regents has authorized the establishment of a fund to be known as the "Dean Maurice H. Rees Scholarship Fund." The scholarship, to consist of tuition and the income from funds donated by students, alumni, faculty and friends, is to be awarded each year to a student entering the junior class of the school of medicine who has shown, in addition to excellent scholarship during his first two years, those fine qualities of character and conscientious devotion to duty manifested by Dean Rees during his lifetime. Dr. Rees, who died May 25, 1945, joined the Colorado faculty in 1921 as professor of physiology and pharmacology, becoming dean in 1925.

ILLINOIS

Seminars on Health Questions.—A series of community relations seminars on health questions, sponsored by the University of Illinois extension service in agriculture and home economics in cooperation with the Illinois state department of public health and the office of state superintendent of public instruction, have been held in seven Illinois cities during January. Meetings were held in Dixon, Pontiac, Springfield, Urbana, Effingham, Benton and Highland. Speakers included Dr. Richard F. Boyd, Springfield, chief of the division of local health administration, state health department.

Chicago

Charles Huggins Goes to Baltimore.—Dr. Charles B. Huggins, professor of surgery (urology) and head of the department of urology, University of Chicago School of Medicine, has been named director of the Brady Urological Institute and professor and head of the department of urology at Johns Hopkins University School of Medicine, Baltimore. The appointment will be effective July 1. The appointment fills the vacancy that occurred when Dr. Hugh H. Young, founder of the Brady institute, died on Aug. 23, 1945. Dr. Huggins, who has been affiliated with the university since 1927, has been professor of urologic surgery at Chicago since 1936. Prior to that he had been associated with the University of Michigan Medical School as instructor in surgery. He graduated at Harvard Medical School, Boston, in 1924.

LOUISIANA

Estrogenic Hormone Creams Forbidden in Louisiana.—The Louisiana State Board of Health on January 11 issued the following order:

> The manufacture, processing, packing, sale or distribution of any cosmetic or beauty preparation containing estrogenic hormone, any of its chemical derivatives or any synthetic chemical product possessing properties similar to estrogenic hormone is hereby prohibited in Louisiana.

Dr. David E. Brown, state health officer, announced that, beginning March 1, action will be taken against all cosmetic preparations containing estrogenic hormone, any of its chemical derivatives or any synthetic chemical product possessing properties similar to estrogenic hormone that are being offered for sale or distribution in Louisiana. The announcement suggests that any one offering for sale or distribution such a product immediately withdraw it from the market in Louisiana.

MARYLAND

Warfield Longcope to Retire.—Dr. Warfield T. Longcope, since 1922 professor of medicine at Johns Hopkins University School of Medicine, Baltimore, will retire June 30, ending twenty-four years' affiliation with the institution. Dr. A. McGehee Harvey, assistant professor of medicine, Vanderbilt University School of Medicine, on leave for service in the army, has been named to succeed Dr. Longcope. Dr. Harvey graduated at Johns Hopkins in 1934.

NEW HAMPSHIRE

John Wheeler New State Health Officer.—Dr. John S. Wheeler, released December 1 from the army with the rank of major, has been appointed state health officer of New Hampshire. He succeeds Dr. Alfred L. Frechette, Concord (THE JOURNAL, Dec. 8, 1945, p. 1036). Dr. Wheeler in 1937 was director of epidemiology and local health in the New Hampshire Department of Public Health. In 1940 he entered the Army of the United States and was stationed in New Hampshire on an assignment with Selective Service. His recent service has been in the Philippines. He graduated at the Boston University School of Medicine in 1930. Dr. Mary M. Atchison, acting deputy health officer in the department, has been appointed deputy health officer.

NEW YORK

Howard T. Ricketts Memorial.—A scrap book exhibiting the research of Dr. Howard T. Ricketts has been presented to the Rochester Academy of Medicine by Mrs. Howard T. Ricketts, Chicago. The book is a photo copy of one shown in a special exhibit at the academy during the dedication of its museum Nov. 16, 1941. In recognition of the gift, Mrs. Ricketts has been made honorary member of the academy.

John Romano Named Professor of Psychiatry.—Dr. John Romano, recently consultant in psychiatry, Army of the United States, European Theater of Operations, and professor of the department of psychiatry and director of service, University of Cincinnati School of Medicine, has been appointed professor of psychiatry at the University of Rochester School of Medicine and Dentistry. He will also be in charge of the new psychiatry clinic to be built in 1946 adjacent to the school's Strong Memorial Hospital. While the new appointment will be effective June 1, Dr. Romano in the interim will visit Rochester periodically to help in the clinic and the staff organization. The cost of the building is estimated at approximately $600,000, and the building cost and an endowment fund of $2,154,000 were given to the school of medicine and dentistry by Mrs. Helen W. Rivas of LeRoy (THE JOURNAL, Nov. 17, 1945, p. 819).

New York City

Medicine's Tomorrow.—An annual symposium on the state of the nation's health, under the title of "Medicine's Tomorrow," was held at the Waldorf-Astoria Hotel January 22 under the sponsorship of the Council of New York University and the faculty of New York University College of Medicine. The speakers were:

Dr. Alfred N. Richards, Philadelphia, The Impact of the War on Medicine.
Dr. Dean A. Clark, New York, Health—the People's Business.
Dr. Alan Gregg, New York, The Mission of a Medical School.

Economics and Medicine.—Dr. Dean A. Clark, Washington, senior surgeon, U. S. Public Health Service, on leave, spoke at a public meeting, January 24, at the New York Academy of Medicine, on "Economics and Medicine." Dr. Clark presented alternative and multiple solutions to the problem of medical costs today when scientific developments have complicated the economics of medicine. He also discussed the economic factors of medical service, the economic position of patients and of physicians, the inadequacy of customary methods of payment, group medical practice, preventive medicine, types of prepayment and the need for joint action on the part of the public and physicians.

Examination for School Psychiatrist.—The board of examiners of the city board of education announced that examinations for the license of school psychiatrist will be given in March. The salary starts at $6,000 and goes to $7,000 in three years. The general requirements are: Age: 30 to 45 years; graduation from an approved medical college and either (*a*) five years of practice in psychiatry including 800 hours in an approved mental institution and 1,200 hours in an approved child guidance clinic or (*b*) three years of practice in psychiatry, including 1,200 hours in an approved mental institution and 1,200 hours in an approved child guidance clinic. Further information about these requirements and the examinations will be obtained with the application. The final date for filing applications is February 25. Application forms may be obtained in person or by writing to Board of Examiners, room 437, Board of Education, 110 Livingston Street, Brooklyn 2. The written request must be accompanied by a large self-addressed envelop bearing 6 cents in stamps.

PENNSYLVANIA

Philadelphia

Gimbel Award Goes to Florence Seibert.—Florence B. Seibert, Ph.D., assistant professor of biochemistry, University of Pennsylvania School of Medicine, on January 3 was presented the $1,000 Gimbel Philadelphia Award for 1945. Dr. Seibert was given the award for her research on tuberculin.

Personal.—Dr. Thomas A. Shallow has been appointed a member of the board of health of Philadelphia and Dr. Nathan Ralph has been appointed medical director of the Country Branch of Rush Hospital for Consumption and Allied Diseases. Both appointments were to fill vacancies that occurred with the death of Dr. John D. McLean.

Charles Zeller Goes to Michigan.—Dr. Charles A. Zeller, superintendent of the Philadelphia State Hospital, has accepted the appointment as director of the Michigan Department of Mental Health, effective March 1. Dr. Zeller graduated at the University of Buffalo School of Medicine in 1927. The Michigan Department of Health, of which Dr. Charles F. Wagg has been acting executive officer, was set up by the 1945 legislature (THE JOURNAL, Nov. 17, 1945, p. 818).

Activities at Woman's Medical College.—Dr. Margaret C. Craighill, dean of the Woman's Medical College of Pennsylvania, has returned from two and a half years of military service. Dr. Craighill, the first woman ever to be commissioned as an officer in the army, has been appointed consultant for the medical care of woman veterans, the first position of its kind in the Veterans Administration. In Dr. Craighill's absence Dr. Marion S. Fay, professor of physiologic chemistry, served the college as acting dean. At the ninety-fourth annual commencement of the college on January 10 two members of the class of 1896 were present to receive a fifty year medal awarded by the Alumnae Association to members of the class, of which there are eleven living members. Dr. Anton J. Carlson, emeritus professor of physiology, University of Chicago School of Medicine, delivered the commencement address, on "The Endless Frontiers in Medicine."

SOUTH DAKOTA

Medical School Adopts Four Year Curriculum.—The first junior students will be admitted to the University of South Dakota School of Medical Sciences, Vermillion, in the spring and the present sophomore class will be the first to continue training at the university, according to the *Journal Lancet.* The expansion of the two year school to a four year curriculum was authorized by the 1945 legislature. Detailed plans for the junior and senior years are being arranged by Dr. Joseph C. Ohlmacher, dean of the medical school, and Edwin H. Shaw, Ph.D., professor of biochemistry, in cooperation with physicians in private practice. Dr. Ralph L. Ferguson, formerly senior pathologist at Edgewood Arsenal, Md., has joined the faculty as professor of pathology and will assist in the organization of the four year course. The Sioux Valley and McKennan hospitals at Sioux Falls will be utilized for the junior year clinical work. The senior year will be organized on a preceptor basis, other hospitals in the state being utilized. The state institutions at Yankton and Sanator will also cooperate in the program.

TENNESSEE

Harrison Shoulders Honored.—The Nashville Academy of Medicine and the Davidson County Medical Society will honor Dr. Harrison H. Shoulders, Nashville, President-Elect, American Medical Association, at a dinner in the Maxwell House Dining Room February 1. Dr. John O. Manier, Nashville, will be the toastmaster and Roger T. Nooe, pastor of the Vine Street Christian Church, Nashville, will deliver the invocation. The speakers will include:

Dr. William C. Chaney Memphis, Greetings from the Tennessee State Medical Association.
Dr. Ernest R. Zemp, Knoxville, The Services of Dr. Shoulders to Tennessee Medicine
Dr. Barney Brooks, Nashville, Greetings from Vanderbilt University Medical School.
Dr. Elmer L. Henderson, Louisville, Plans Proposed by American Medicine for Distributing the Cost of Medical Care on a Voluntary Basis.
Dr. Ernest E. Irons, Chicago, Socialized Medicine from a Historical Point of View.
Dr. Irvin Abell, Louisville, Legislative Proposals and Their Threat to Quality Medical Care.
Dr. Olin West, Chicago, The American Medical Association: Its Organization and Purposes.

TEXAS

The Hite Fellowships in Science.—The board of regents of the University of Texas has established four postdoctoral and ten predoctoral fellowships in the fields of science relating to cancer. In June 1944 Miss Rosalie B. Hite, Houston, bequeathed to the University of Texas the bulk of her estate with instructions that the income be used in researches into the cause, prevention, treatment and cure of cancer. The new fellowships are the result. Known as the Rosalie B. Hite Fellowships, they are to be awarded to properly qualified persons who have a doctoral degree (or the equivalent in training) and who wish to do or to continue research work which can qualify under a liberal interpretation of the terms of the bequest, or graduate students who desire to fit themselves to do research in fields which will contribute to the fundamental knowledge of normal and abnormal cells. It is the belief of the board that one of the great needs in cancer research today is a clearer understanding of how normal cells function, for without this knowledge workers in cancer research are greatly handicapped in their efforts to comprehend the cause, or causes, of abnormal behavior. With this point of view in mind, preference will be given to persons who desire training in the borderline fields of biology and the physical sciences, such as cytochemistry, biophysics, enzyme and protein chemistry and related biochemical fields. To be eligible for postdoctoral fellowships, a person must have a doctor's degree (or the equivalent in training) and have demonstrated competence in research. A stipend of $2,400 per calendar year (including a vacation of six weeks) is given in such cases. The holders of these fellowships will not be required to pay fees to the university. Research work may be carried on at the main university at Austin, at the M. D. Anderson Cancer Research Hospital at Houston or at the school of medicine at Galveston, depending on which branch of the university best serves the interests of the investigator as approved by the committee of award. An applicant for a predoctoral fellowship must have graduated with high scholastic standing from an institution of higher learning and must have had thorough training in the fundamentals of biology and chemistry so that he can profitably begin work at once in one or both of these fields at the graduate level. The stipend of the predoctoral fellowships will be $100 per month net; that is, the university will pay all fees. In case a person desires to continue work for an entire calendar year, a vacation of six weeks with pay will be allowed. While the award of these predoctoral fellowships is on an annual basis, it is desired that the holder who demonstrates satisfactory progress will be allowed a reasonable time in which to receive his doctor's degree. It is obligatory that the thesis problem come within a liberal interpretation of the terms of the Hite bequest. Applicants should write for blanks and further information by February 1. All applications must be received in final form by March 1. The committee of award will make selections by April 1, and applicants will have until April 15 for acceptance. All inquiries should be addressed to the Dean of the Graduate School, University of Texas, Austin 12, Texas.

GENERAL

Urologic Award.—The American Urological Association offers an annual award, not to exceed $500, for an essay (or essays) on the result of some specific clinical or laboratory research in urology. The amount of the prize is based on the merits of the work presented, and, if the committee on scientific research deems none of the offerings worthy, no award will be made. Competitors will be limited to residents in urology in recognized hospitals and to urologists who have been in such specific practice for not more than five years. All interested should write the secretary for full particulars. The selected essay (or essays) will appear on the program of the meeting of the American Urological Association to be held at the Netherland Plaza, Cincinnati, July 22-25. Essays must be in the hands of the secretary, Dr. Thomas D. Moore, 899 Madison Avenue, Memphis, on or before July 1.

Research Medal Goes to Tinsley Harrison.—The Research Medal of the Southern Medical Association was presented to Dr. Tinsley R. Harrison, professor of internal medicine, chairman of the department, and dean, Southwestern Medical College, Dallas, during the thirty-ninth annual meeting of the Southern Medical Association in Cincinnati, November 12-15. The award went to Dr. Harrison "in recognition of his outstanding contributions toward the elucidation of structural and functional aspects of cardiovascular disease and particularly of practical problems arising from failure of the circulation." Dr. Elmer L. Henderson, Louisville, was chosen president-elect of the Southern Medical Association and Dr. Marye Y. Dabney, Birmingham, Ala., was installed as president. Vice presidents are Dr. Lucien A. LeDoux, New Orleans, and Dr. Oscar W. Frickman, Newport, Ky. Mr. C. P. Loranz, Birmingham, Ala., is secretary-manager.

Conference on Medical Service.—The nineteenth annual meeting of the National Conference on Medical Service will be held at the Palmer House, Chicago, February 10, under the presidency of Dr. Chauncey L. Palmer, Pittsburgh, who will discuss "Medicine and the National Crisis." Other speakers on the program will include:

Mr. J. S. Jones, St. Paul, What the Farmer Expects from Medicine.
Mr. Howard Strong, Washington, D. C., What Industry Expects from Medicine.
Major Gen. Paul R. Hawley, Washington, Medical Care of Veterans.
Dr. Andrew S. Brunk, Detroit, Aims and Purposes of Conference of Presidents and Other Officers of State Medical Societies.
Dr. Victor S. Johnson, Chicago, What About Returning Medical Officers? Postgraduate Opportunities.
Mrs. M. Virginia Shuler, Chicago, Establishment of State Bureaus of Information.
Mr. J. W. Holloway Jr., Chicago, Medical Legislation.
Mr. Jay C. Ketchum, Detroit, National Plan for Volunteer Prepayment Medical Care.

International Congress on Mental Deficiency.—At the sixty-ninth annual meeting of the American Association on Mental Deficiency in Cleveland, November 28-December 1, it was decided to hold the first International Congress on Mental Deficiency in Boston in 1948, probably in May or June. The congress would observe the one hundredth anniversary of the establishment in Massachusetts in 1848 of the first American school for the mentally subnormal. Two were founded in the same year, one at Barre, a private school, and one at South Boston, the first state school. The latter has since moved to Waverly and is known as the Walter E. Fernald State School. The chairman of the international congress is Dr. Charles Stanley Raymond, superintendent of the Wrentham State School, Wrentham, Mass. Officers of the American Association on Mental Deficiency chosen at the recent meeting are Dr. Warren G. Murray, Dixon, Ill., president-elect; Miss Mabel Matthews, Hartford, Conn., president, and Dr. Neil A. Dayton, Mansfield Depot, Conn., secretary-treasurer. Future meetings of the association are to be at Montreal, October 2-5, St. Paul in 1947 and Boston in 1948.

Didactic Course for Ophthalmologists.—The Ophthalmological Study Council was organized at a meeting in Boston January 5 to furnish a course for ophthalmologists returning from military service, to be given at the Boston Medical Library. The course will be designed for those wishing to practice the specialty of ophthalmology but who cannot secure instruction to meet the requirements of the American Board of Ophthalmology at any of the existing institutions because present facilities are wholly inadequate. The program is not intended to supplant the existing university courses but to meet an emergency. The following is a condensed outline of the subjects to be covered:

April 1-May 1—Anatomy, Histology, [illegible] [illegible], Bacteriology, Pharmacology, Physiology, Sensory [illegible] [illegible], Perimetry. In the evening, Optics, Physiologic Opti[illegible] of view including Image Formation, Aberrations, Accommodation, Astigmatism and Errors of Refraction.

May 1-June 1—Pathology, Bio-chemistry, Physiology, Light Sense, Color Sense, Form Sense, Allergy. In the evening, Motor Neuro-Ophthalmology, Ocular Motility, Normal and Abnormal, Strabismus of all kinds, Binocular Vision, Space Perception, Orthoptics.

An adequate faculty is assured. Applicants must have acceptable medical training and ethical standing (membership in county medical society). The number will not be limited. This is not a laboratory or clinical course. Instruction is by lectures, required reading, quizzes and seminars and is preparatory to and in addition to the necessary clinical training in residency or preceptorship. Applications should be made to the Ophthalmological Study Council, 520 Commonwealth Avenue, Boston 15, Mass. Mention should be made of premedical and complete medical training with dates; also military service, if any, and whether or not a candidate for the American Board of Ophthalmology. The new council has the following executive officers: Drs. Walter B. Lancaster, Hanover, N. H., Theodore L. Terry, Boston, S. Judd Beach, Portland, Maine, from whose suggestion the council stemmed, and Trygve Gundersen, Brookline, Mass. This new type of course is patterned after one conducted in Oxford by Dr. Ida Mann, head of the new Ophthalmologic Institute there and the first woman to be given the title of professor at Oxford.

Commonwealth Fund Fellowships to General Practitioners.—The Commonwealth Fund has announced the conditions governing its postgraduate fellowships offered to general practitioners during 1946. Fellowship aid is to be limited to honorably discharged physicians who have seen service for six months or longer, since 1940, in the armed forces of the United States and who plan to take up residence and to practice in a community having a population of 25,000 or less situated in Mississippi, Oklahoma or Tennessee. Physicians who qualify may be considered for a fellowship which provides postgraduate study for one to four months at an approved institution. The course or courses of study shall be subject to approval by the fund and may include general medicine and diagnosis, pediatrics, obstetrics, medical gynecology or minor surgery, or combinations of two or more of these subjects. The fund is not to assume responsibility for the registration of a fellow in a particular course; this arrangement must be made by the individual with the institution where the work is offered. Courses are to be taken in continuous term and are not to depart from the approved schedule without special authorization. The applicant must be a graduate of a reputable medical school and have completed a satisfactory internship. He must furnish a record of a recent physical examination, and a personal interview with a member of the fund staff may be required. The rate of the fellowship is to be uniform at $100 a month for the duration of the award, one to four months. Applications for fellowship are to be made on forms furnished by the Commonwealth Fund, Division of Public Health, 41 East 57th Street, New York 22.

Research Foundation Enters Consent Decree on Vitamin Suit.—Attorney General Tom C. Clark announced the entry in the United States District Court at Chicago of a consent judgment terminating a civil antitrust suit against the Wisconsin Alumni Research Foundation and seventeen other firms. As part of the settlement of this case the Attorney General stated that the vitamin D patents owned by the Wisconsin Alumni Research Foundation have been dedicated to the public. The government's suit, filed on Oct. 20, 1944, charged the Wisconsin Alumni Research Foundation and seventeen of its so-called licensees in the chemical, drug, packaged foods and evaporated milk fields with unlawfully conspiring to restrain and monopolize trade and commerce in vitamin D and vitamin D products in violation of the Sherman Antitrust Act. The court's decree was entered with the consent of the Department of Justice and the defendant Wisconsin Alumni Research Foundation. It enjoins the foundation from instituting suits for infringement or to collect royalties based on any of the patents dedicated to the public and also enjoins the foundation from entering into any future licensing of patents relating to vitamin D which provide for price fixing or impose restrictions on the manufacture, use or sale of vitamin D or vitamin D products. In addition to dedication to the public of the vitamin D patents, the foundation has canceled the restrictive patent agreement which the government had attacked in its complaint. Among the patents dedicated to the public are those obtained by Harry Steenbock, Ph.D., professor of biochemistry at the University of Wisconsin, Madison, on the manufacture and use of vitamin D, the so-called "sunshine vitamin," which prevents and cures rickets. Wendell Berge, assistant attorney general in charge of the antitrust division, in discussing the allegation in the government's complaint said: The complaint charged that arbitrary and unreasonable prices of pharmaceutical vitamin D products had been maintained so that persons who most needed vitamin D to prevent and cure rickets were unable to obtain it. In this connection it stated that for at least seven years prior to 1944 the cost of manufacturing vitamin D was less than $0.15 per million units but that the five pharmaceutical manufacturers who were involved had sold the product to wholesalers at prices between $2.65 and $7.70 per million units and the public was charged between $3.35 and $10.80 per million units for the same product. It also charged that the conspiracy resulted in a limitation of the potency of vitamin D food products in order to prevent them from competing with vitamin D pharmaceutical products, with the result that the normal consumption of a vitamin D food product would not cure, although it might prevent rickets. The government has recommended to the court that the suit be dismissed as to those defendants who have canceled their restrictive agreements with the foundation. Those defendants are:

E. I. du Pont de Nemours and Company
The Quaker Oats Company
Standard Brands Incorporated
Gelatin Products Corporation
The Borden Company
Carnation Company
Pet Milk Company
Indiana Condensed Milk Company
Nestle's Milk Products, Inc.
Vitamins, Inc.
Abbott Laboratories
Mead Johnson and Company
The William S. Merrell Company
Parke, Davis and Company
E. R. Squibb and Sons
Winthrop Chemical Company, Inc.

Deaths

Don Welsh Gudakunst ⊕ White Plains, N. Y., medical director of the National Foundation for Infantile Paralysis, died suddenly in Chicago, January 20, aged 51.

Dr. Gudakunst was born in Paulding, Ohio, Aug. 18, 1894. He studied in Toledo and Somerville, Mass., graduating at the University of Michigan School of Medicine, Ann Arbor, in 1919. After internship at the University Hospital in Ann Arbor Dr. Gudakunst became industrial physician for the Solway Process Company, Detroit, in 1920, and health officer of Chaves County in Roswell, N. M., the following year. In 1924 he returned to Detroit, where he served as director of the school health service of the city health department until 1937 and as deputy health commissioner from 1932 to 1937. The following year he became commissioner of the Michigan State Department of Health. During this period Dr. Gudakunst was also professor of public health and preventive medicine at Wayne University School of Medicine, Detroit. At one time he was a senior surgeon (R), U. S. Public Health Service.

Since his appointment as medical director, Jan. 1, 1940, Dr. Gudakunst had worked indefatigably in the development of the National Foundation for Infantile Paralysis. He was an Associate Fellow of the American Medical Association and a member of numerous scientific groups. He had also written extensively on many medical topics, and particularly on infantile paralysis.

Stanley Rogers Woodruff ⊕ Bayonne, N. J.; Yale University School of Medicine, New Haven, 1897; born in Orange, Conn., in 1875; specialist certified by the American Board of Urology, Inc.; clinical professor of urology at the New York Polyclinic Medical School and Hospital, New York; member of the American Urological Association; fellow of the American College of Surgeons; past president of the board of education; chairman, Section on Urology of the American Medical Association, 1934-1935; attending genitourinary surgeon, Bayonne (N. J.) Hospital and Christ Hospital, Jersey City; consulting urologist at the following hospitals: Greenville, Jersey City; St. Mary's, Hoboken; Hackensack, Hackensack; Elizabeth A. Horton Memorial, Middletown, N. Y., and St. Vincent's, Staten Island, N. Y.; died October 13, aged 70, of bronchopneumonia and carcinoma of the prostate.

Theodore John Dimitry ⊕ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1901; professor of ophthalmology and director of the department at the Louisiana State University School of Medicine; served as a lecturer on special anatomy at the Loyola University and vice president and professor of ophthalmology at the Loyola Post-Graduate School of Medicine; specialist certified by the American Board of Ophthalmology; fellow of the American College of Surgeons; a regent of the International College of Surgeons; served on the staffs of the Charity Hospital, New Orleans Hospital and Dispensary for Women and Children, De Paul Sanitarium, Hotel Dieu and the Mercy Hospital-Soniat Memorial; died in the Baptist Hospital October 27, aged 66, of coronary thrombosis.

Harry Hedgewick Drysdale ⊕ Cleveland; University of Wooster Medical Department, Cleveland, 1901; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association and the Cleveland Academy of Medicine; veteran of the Spanish-American War; a consulting member of the medical advisory board during World War I and medical examiner for the induction board during World War II; served with the U. S. Public Health Service; consultant in neuropsychiatry, St. Vincent Charity Hospital; at one time assistant superintendent of the Massillon (Ohio) State Hospital; died October 5, aged 69, of cardiac asthma.

John Gaskin Dunlop ⊕ Los Angeles; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1929; member of the American Society of Anesthetists, of which he had served as assistant secretary; formerly assistant professor of anesthesia at the College of Medical Evangelists; a fellow in anesthesia of the Mayo Foundation in Rochester, Minn., from May 14, 1931 to Sept. 15, 1934; interned at the Orange Memorial Hospital in Orange, N. J.; a member of the staff and in 1944 resigned as secretary of executive staff, Hospital of the Good Samaritan; died October 15, aged 42, of rheumatic heart disease.

Fredric Lewis, Stamford, Conn.; Long Island College of Medicine, Brooklyn, 1936; served an internship and residency at the Harlem Hospital in New York, where he also served an internship at the French Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on May 30, 1941; promoted to captain; served as flight surgeon with the Sixth Air Force in Panama; relieved from active duty June 8, 1944; on the staffs of the Stamford and St. Joseph hospitals; died in the Mount Sinai Hospital, New York, October 4, aged 36, of carcinoma.

Roland Orlando Bagby, Kansas City, Mo.; Kansas City College of Medicine and Surgery, 1920; member of the American Medical Association; died in the Research Hospital October 10, aged 59, of brain abscess.

Miles John Breuer ⊕ Los Angeles; Rush Medical College, Chicago, 1915; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians and the American Society of Clinical Pathologists; member of the American Heart Association and National Tuberculosis Association; served during World War I; at one time on the staffs of the Bryan Memorial, Lincoln General and St. Elizabeth hospitals all in Lincoln, Neb.; died in the National Military Home October 14, aged 56, of uremia.

Otto Budde, Chicago; Northwestern University Medical School, Chicago, 1895; died October 24, aged 81, of heart block and arteriosclerosis.

James Tweedie Campbell, Chicago; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1889; Bellevue Hospital Medical College, New York, 1889, and member of the Royal College of Surgeons of England, 1890; formerly professor of laryngology, rhinology and otology at the Post-Graduate Medical School and Hospital; senior attending rhinologist, otologist and laryngologist at St. Luke's Hospital, where he had been a member of the staff since 1907; died October 26, aged 79, of diabetes mellitus.

James Francis Carty Jr., New York; University of Pennsylvania School of Medicine, Philadelphia, 1942; interned at St. Francis Hospital in Hartford, Conn.; served a residency at the Memorial Hospital, where he died September 24, aged 29, of lymphosarcoma.

Mortimer Thomas Cavanaugh ⊕ Great Barrington, Mass.; Baltimore Medical College, 1898; served during World War I; for many years a member and chairman of the board of health, and school committee; medical examiner for the Great Barrington district; chief of staff, Fairview Hospital; died October 7, aged 73, of coronary occlusion.

Howard L. Clarke ⊕ La Cygne, Kan.; Kansas City (Mo.) Medical College, 1898; died in the Lawrence Memorial Hospital, Lawrence, October 19, aged 76, of carcinoma of the descending colon.

Albert Woods Dumas Sr., Natchez, Miss.; Illinois Medical College, Chicago, 1900; past president of the National Medical Association and member of advisory board to editorial staff of its journal; member of the advisory committee on child and maternal welfare, Children's Bureau; died October 1, aged 69, of cerebral hemorrhage.

Robert Franklin Elrod, Fort Payne, Ala.; Chattanooga (Tenn.) Medical College, 1905; acted as county health officer; member of the American Medical Association; died October 18, aged 63, of coronary thrombosis.

Frederick Gochnauer, Upperville, Va.; University College of Medicine, Richmond, 1903; member of the American Medical Association; member of the county board of health; on the staff of the Winchester Memorial Hospital in Winchester, where he died October 9, aged 66, of coronary thrombosis following an operation.

Frank Branch Gooch ⊕ Houston, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1916; served during World War I; on the visiting staffs of the Methodist and Memorial hospitals and St. Joseph's Infirmary; died October 8, aged 57, of coronary occlusion.

Herbert Collins Hanning ⊕ Dayton, Ohio; College of Physicians and Surgeons, Baltimore, 1894; past president of the Montgomery County Medical Society; member of the House of Delegates of the American Medical Association in 1912 and 1913 and from 1915 through 1918; at one time a member of the city board of health; died October 17, aged 77, of ruptured gallbladder.

Everett Arnold Land ⊕ Norfolk, Va.; University College of Medicine, Richmond, 1906; fellow of the American College of Surgeons; member of the Selective Service Board; on the staffs of the Leigh Memorial and Norwalk General hospitals; died October 30, aged 65, of heart disease.

Philip Le Sage, Joliet, Ill.; Chicago Medical College, 1890; in 1941 honored at a meeting of the Will-Grundy Counties Medical Association and presented with a fifty year medal and diploma commemorating his half a century in the profession; on the staffs of St Joseph's and Silver Cross hospitals; died September 24, aged 79, of arteriosclerosis.

Stephen C. Lewis, St. Petersburg, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; for many years a medical missionary in China; died in Grove City, Pa, October 21, aged 76, of adenocarcinoma of the liver.

Joseph O'Connell, Oconomowoc, Wis.; Rush Medical College, Chicago, 1903; on the staff of St. Mary's Hospital in Watertown; died September 27, aged 73.

Aaron H. Rabinovitz ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1914; died in the Jewish Hospital September 6, aged 71, of cerebrovascular disease.

Anthony John Schneider ⊕ Indianapolis; Medical College of Indiana, Indianapolis, 1898; on the staff of St. Francis Hospital; died October 9, aged 70, of injuries received when the automobile in which he was driving was struck by a train.

Orlando J. Shank, Windber, Pa.; Baltimore Medical College, 1896; surgeon for the Pennsylvania Railroad; member of the American Medical Association; served as postmaster, president of the board of health and school examiner; died September 23, aged 76, of coronary occlusion.

Herman Cecil Smith, Liberty, Texas; State University of Iowa College of Medicine, Iowa City, 1896; died in September, aged 78.

Mansfield Leonidus Spears ⊕ Pontiac, Mich.; Meharry Medical College, Nashville, Tenn., 1917; died in St. Joseph Mercy Hospital September 16, aged 55.

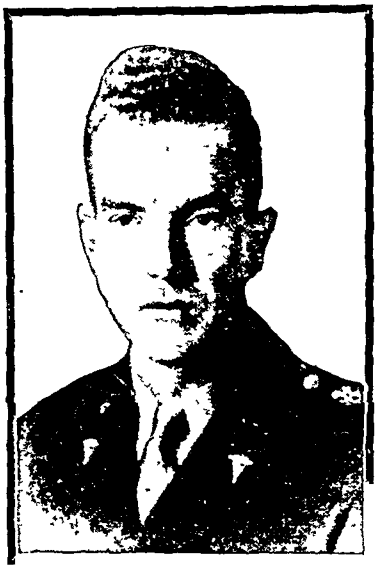
Homer Sylvanus Stallings ⊕ Troy, Ala.; Atlanta College of Physicians and Surgeons, 1902; died in the Edge Hospital September 19, aged 70, of cerebral hemorrhage.

John H. Terhorst, Milwaukee; Northwestern University Medical School, Chicago, 1894; died September 20, aged 76, of coronary arteriosclerosis.

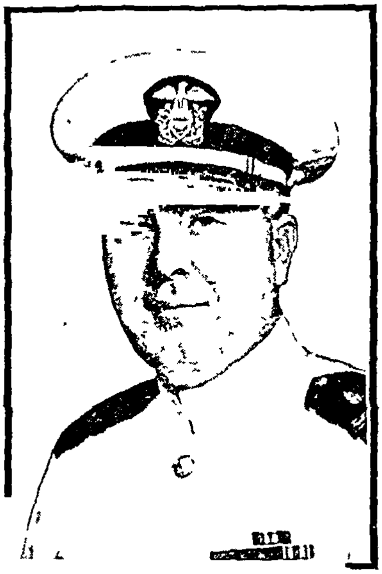
Austin Hulbert Thomas, Ironwood, Mich.; Rush Medical College, Chicago, 1883; served as physician to Newport Mining Company; died in Winneconne, Wis., September 7, aged 90, of arteriosclerotic heart disease.

William Remsen Varick, Santa Barbara, Calif.; Columbia University College of Physicians and Surgeons, New York, 1895; for four years a member of the Selective Service Board; member of the board of directors of the Cottage Hospital; died November 9, aged 74, of carcinoma.

MAJOR WILLIAM HART HOUSTON JR.
M. C., A. U. S., 1911-1944



CAPT. ROBERT BARNES WARE
M. C., A. U. S., 1914-1944



LT. COMDR. CLYDE LIONEL WELSH
(MC), U.S.N.R., 1899-1944

Irvin W. Shollenberger, Reading, Pa.; Baltimore Medical College, 1901; formerly on the staff of the Reading Hospital; died September 15, aged 69, of injuries received in an automobile accident.

Allen Alfred Yoder, Akron, Ohio; Medico-Chirurgical College of Philadelphia, 1898; died in the Akron City Hospital November 13, aged 75, of ruptured abdominal aneurysm and arteriosclerosis.

KILLED IN ACTION

William Hart Houston Jr., Palo Alto, Calif.; St. Louis University School of Medicine, 1937; interned at San Francisco Hospital; served a residency at the University Hospital in Ann Arbor, Mich.; entered the medical reserve corps of the U. S. Army as a first lieutenant on June 1, 1937; began active duty in the same rank in the medical corps, Army of the United States, on Feb. 3, 1941; promoted to captain and major; had been overseas with the paratroopers since April 1943, engaging in the Sicily and Italy campaigns; awarded the Legion of Honor posthumously "for exceptionally meritorious conduct in the performance of outstanding services as commanding officer of an airborne medical company, 82d Airborne Division, from August 15, 1942 to June 6, 1944"; killed in action in France June 6, 1944, aged 33.

Robert Barnes Ware, Lynchburg, Va.; Medical College of Virginia, Richmond, 1940; interned at the Lynchburg General Hospital; called to active duty as a first lieutenant in the medical reserve corps of the U. S. Army on July 1, 1940; assigned to duty at Fort George G. Meade, Md; promoted to captain in the medical corps, Army of the United States; had been overseas since Sept. 27, 1942; killed in action in France June 6, 1944, aged 29.

Clyde Lionel Welsh, Seattle; Tulane University of Louisiana School of Medicine, New Orleans, 1928; member of the American Medical Association and the Pacific Coast Oto-Ophthalmological Society; interned at the Ancker Hospital in St. Paul; served as resident physician at the Bismarck Hospital and Deaconess Home in Bismarck, N. D., and the University of California Hospital, San Francisco; began active duty as a lieutenant commander, medical corps, U. S. Naval Reserve, on Nov. 1, 1940; assigned to Eye, Ear, Nose and Throat Department at the U. S. Naval Hospital, Canacao, P. I.; taken prisoner by the Japanese on Jan. 1, 1942 and remained in Bilibid Prison as chief of medicine until Dec. 12, 1944; killed at Tacao, Formosa, Dec. 15, 1944, aged 45, by a direct bomb hit while being transferred to Japan on a Japanese prison ship.

Vital Statistics for the Last Year of the War

The annual summary report of the Ministry of Health for the year ended March 31, 1945 has just been published. It confirms previous reports of improved vital statistics during the war. The death rates of women in childbirth, babies in the first month of life and children up to 5 years of age were the lowest ever recorded in England and Wales, as were the death rates of tuberculosis, diphtheria, typhoid and the standardized death rates for men and women. The birth rate reached 18 per thousand of population for the first time in nineteen years. The infant mortality was 46 per thousand live births, 3 less than the record low figure for 1943. The neonatal mortality rate was 24.5, the lowest ever recorded, being 0.7 below that of 1943 and 3.8 below the rate in 1938 and 1939. The death rate of the civilian population was 9.42 for males and 6.63 for females, the lowest ever recorded. The previous low record was 9.53 and 6.84 respectively in 1942. The maternal mortality rate, including deaths from abortion, declined to 1.95 per thousand births. The deaths from all forms of tuberculosis numbered 24,163, the lowest ever recorded. The usual wartime increase in the number of cases of tuberculosis took place in 1942 and 1943 but was checked in 1944. The number of persons examined by mass radiography up to March 1945 was over 400,000. About 4,000 were found to have tuberculosis or were suspected cases. For the third successive year there was a substantial decrease in the notifications of and deaths from diphtheria; 29,949 were notified, and 934 persons died, less than a third of the average for the prewar decade. The decrease, which has been continuous since 1941, must be credited to immunization. During the year over half a million children were immunized, but this is still not satisfactory, since this number is only a little over half the births of the previous year.

The Problem of Rickets

Rickets is no longer a common disease in Britain, because of improved methods of feeding. A special inquiry by the British Pediatric Society, by arrangement with the Ministry of Health, showed, however, that wartime conditions had produced some increase of the disease. Owing to the lack of sunshine in this country, the deficiency of vitamin D is a nutritional problem. Because of the mild form in which rickets now occurs, the diagnosis is extremely difficult. When there are only minor bone signs clinical diagnosis may be impossible. Radiology is then of great help, and in doubtful cases it should be supplemented by determination of the blood phosphatase. For prevention and treatment the memorandum gives specific instructions. In order to prevent rickets it is recommended that babies, however fed, should receive a supplement of vitamin D in daily doses of 500 to 800 international units, given in the form of cod liver oil. For the treatment of active rickets ultraviolet irradiation should be combined with larger doses of vitamin D than those recommended for prophylaxis.

The Stethoscope versus the X-Rays

At the Section of Medicine of the Royal Society of Medicine there was an important discussion by physicians and radiologists on the use of the stethoscope and x-rays. Dr. James Maxwell remarked that many doctors falsely assumed that if pathologic physical signs were not detected in the chest there was nothing wrong. The absence of these signs does not exclude tuberculosis or early bronchial carcinoma, both curable if detected before physical signs are present. Students should be taught the x-ray appearance of the normal chest and its variations. Often the x-ray film will reveal a lesion which physical examination will miss, and sometimes the converse will be true. A practitioner who does not insist on x-ray examination of a suspected chest, especially after hemoptysis, might be sued for negligence.

Dr. Peter Kerley believes that the stethoscope has limited uses so that radiography should be considered indispensable. Views in three directions and tomography are essential for a proper interpretation. However, the stethoscope is superior in the diagnosis of heart conditions. Contrast mediums for angiography will soon be made completely safe, and then radiologists will be able to demonstrate chambers of the heart and the pulmonary circulation.

Dr. Geoffrey Marshall felt that there was no reason for discarding either instrument but he considered the x-rays more valuable. The stethoscope was important as an adjunct to radiography.

In the discussion there was general agreement between physicians and radiologists that the stethoscope is valueless in the majority of cases of early pulmonary disease. Many thought that too much emphasis was still placed on obsolete stethoscopic signs. Potential advances in chest radiography may soon lead to large condenser discharge machines with focal spot measures in fractions of a millimeter, so that not only great increase in detail but double and quadruple magnification of suspected areas may be obtained.

Frequency of Cancer in France

In an article recently published in the *Archives de médecine sociale* Professor Huguenin states that cancer mortality in France was 60,500 deaths in 1943 and 51,810 in 1936. This is a rate of 161 per hundred thousand inhabitants for 1943. Women represent 56 per cent of the cases and men 44 per cent. Cancer of the uterus is the most common, comprising 24 per cent, and the least frequent is cancer of the urinary system, with 1 per cent. The rate of mortality is higher than for tuberculosis (140 per hundred thousand inhabitants) in 1943, with a total of 55,000 deaths. Five thousand children under 15 years of age lose either their father or their mother each year through cancer. Mortality from cancer is not the same throughout the country; its rate varies from 175 to 200 per hundred thousand inhabitants in the center of France; it is under 125 or from 125 to 150 in the South and from 150 to 175 in the North and the Southeast. A new fact, found generally, is the diminution of the age of cancerous people This phenomenon, emphasized by Huguenin at the Academy of Medicine, is seen especially among repatriated military prisoners. In this case traumatism plays a part, as was seen after the war of 1914-1918. Of 501 repatriated cancerous people, 6 were under 20 years of age, 64 were from 20 to 30 years old, 268 from 30 to 40 years and 163 over 40 years of age, or 338 patients under age 40.

French Association for the Advancement of Science

Among the numerous foreign delegates at the sixty-fourth congress of the French Association for the Advancement of Science were Richard Gregory Bart, president of the British Association for the Advancement of Science, Edward Appleton, secretary of the Department of Scientific Research, Professor Albrecht, vice president of the American Association for the Advancement of Science and Professors Dean Amory Worcester of Nebraska, Stanley Adair Cain of Tennessee and Capt. Alvin Russell Grove of Pennsylvania and Professors Nesmeianov and Landsberg of the Russian Academy of Sciences. The congress had organized its work in sections. medical sciences, Professor

Baudoin president; electroradiology, Professor Strohl president; pharmacology, Professor Hazard president; hygiene and public health, Dr. Leclainche president. The next congress will be held at Nice in 1946.

BRAZIL

Rio de Janeiro, Dec. 14, 1945.

Malignant Tumors in Gynecology

In a recent paper published to commemorate the tenth anniversary of Dr. Arnaldo de Moraes's tenure of the post of professor of Clinical Gynecology at the University of Rio de Janeiro, Dr. Hildegard Stoltz, assistant in the service, reviewed 277 malignant tumors in women treated during this decade in Dr. de Moraes's department. The 277 tumors occurred in 3,120 women, an incidence rate of 8.9 per cent. In this total the author does not include cases in which the biopsy, repeated several times, did not afford sufficient foundation for a definite diagnosis of cancer. The cancerous lesions were in the cervix of the uterus in 220 cases (79.4 per cent), body of the uterus in 10 cases (3.3 per cent), cervical canal in 4 cases (1.4 per cent), vagina in 9 cases (3.3 per cent), ovary in 8 cases (2.9 per cent), vulva in 4 cases (1.4 per cent), mammary glands in 13 cases (5.0 per cent), rectum in 5 cases (1.8 per cent), sigmoid colon in 1 case (0.4 per cent), mesentery in 2 cases (0.7 per cent) and bladder in 1 case (0.4 per cent).

During the first years of this ten year period, besides palliative therapy, surgery alone could be used with radium therapy in some cases. Roentgen therapy was not begun until 1938. Treatment of 277 cases was by surgery alone in 32 cases (11.5 per cent), surgery and radium therapy in 6 (2.1 per cent), surgery and roentgen therapy in 14 (5.0 per cent), surgery, radium therapy and roentgen therapy in 1 case (0.3 per cent), radium therapy alone in 101 cases (36.5 per cent), radium therapy and roentgen therapy in 39 cases (14.1 per cent), roentgen therapy alone in 9 cases (3.2 per cent) and palliative treatment alone in 75 cases (27.3 per cent).

Special Medical Courses

At the University of Rio de Janeiro Dr. A. Marques Torres of the Oswaldo Cruz Institute is giving a course for students and physicians on modern aspects of infectious and parasitic diseases. Dr. Claudio Bardy, associate professor of medicine at the same university, is giving a special course on clinical radiology.

The Center of Medical Studies of the Misericordia Hospital, founded last year by the late Dr. Paulo Cesar de Andrade and now bearing his name, is giving several special courses, among which are dietetic treatment of diseases of the digestive apparatus (Dr. Geraldo Seiffert), diagnosis of the diseases of the digestive system (Dr. L. Capriglione) and clinical cardiology (Dr. Magalhães Gomes).

The division of specialization courses of the National Department of Health is now giving, for physicians of several states of Brazil, lectures and demonstrations on mental hygiene and clinical psychiatry, cancer, vital statistics, malaria, trachoma, modern diagnosis of tuberculosis and venereal diseases.

Hospital News

Some time before the entrance of Brazil into the war in 1942 the federal government created in Rio de Janeiro the Central Hospital of the Brazilian Air Force, an institution that probably is today the best hospital of its kind in South America. A private hospital was requisitioned and under the able direction of Colonel Edgard Tostes, one of the first Brazilian physicians to be trained in the United States as an air surgeon, it was enlarged and greatly improved. The hospital has now the new equipment developed during the war in Europe and in the United States, particularly in the field of surgery. Later the government decided to establish several other hospitals in connection with the new air bases: one hospital was opened some months ago in Belem in the state of Pará. Another is to be established in the southern part of the country, perhaps in the state of Paraná.

The Butantan Institute of São Paulo has set up a hospital for the specific treatment of patients suffering from attack by venomous animals, especially snakes.

The Division of Hospital Organization of the National Department of Health has published a booklet entitled "Primer of Modern Hospital Organization," written by Dr. Theophilo de Almeida. This is the second of a series of publications designed to improve the hospital situation in Brazil. Dr. de Almeida has been in the United States for some time studying the organization of American hospitals.

The great Pedro Ernesto General Hospital has been temporarily transferred to the University of Rio de Janeiro, until the construction of University City, a project that the federal government is about to begin.

The legislative assembly of the state of Pernambuco has approved an appropriation for the construction of a hospital for emergency cases at Recife (385,000 population), the capital city of the state. A new corporation has been formed to build a general hospital also in this city. The medical superintendent of the institution, the Santa Catharina Hospital, is Dr. Alberto Borgerth, a leading surgeon of the department of hospitals of Rio de Janeiro.

A division of plastic surgery has been inaugurated at the Hospital das Clinicas, an institution associated with the University of São Paulo. The division will be directed by Dr. Carlos C. Cortese in the department of surgery under the supervision of Professor Edmundo Vasconcellos.

A department of roentgen therapy has been inaugurated at the Moncorvo Filho Hospital of this city. The equipment was a gift from Mr. Mario de Almeida, an industrialist of Rio de Janeiro.

The Hospital Nossa Senhora das Dores of Cascadura, a northern suburb of Rio de Janeiro, has been remodeled to offer better care to dependent tuberculous patients. The x-ray department was one of the sections particularly improved.

Dr. Miguel Couto Filho has donated to the state of Rio de Janeiro land at Cabo Frio, where the state administration is planning to build a modern hospital for crippled children.

Marriages

Robert T. Miller, New York, to Miss Mary Catharine Bolster of Goldsboro, N. C., in Richmond, Va., November 3.

Lucien Michele Pascucci, Waterbury, Conn., to Miss Marcella Ann Czajkowski of St. Louis, November 10.

Joe Henry McCormick Jr., Monroe, La., to Dr. Thiesen Agatha Ray of Charleston, S. C., November 13.

Myers Hampton Hicks to Miss Edith Monroe McEachern, both of Florence, S. C., in November.

Richard Bruce O'Bryan, Columbus, Ind., to Miss Mary Alice Pesch of Plymouth, August 25.

William E. Mitchell, Memphis, Tenn., to Miss Louise Davis of Chaffee, Mo., in November.

William Roy Green, Tupelo, Miss., to Miss Helene Maxine White of Victoria, Va., October 29.

William Maurice Cannon to Miss Theoleen Gantt, both of Charleston, S. C., October 17.

George T. Wohl to Dr. Norma Spielman, both of Philadelphia, November 17.

Nevin E. Aiken to Miss Barbara Botts, both of Fort Wayne, Ind., July 9.

Samuel S. Leiter to Miss Beverly Agins, both of Philadelphia, October 21.

John H. Kneidel to Miss Jean Lou Foley, both of Indianapolis, July 14.

DIFFERENTIAL DIAGNOSIS OF ECTODERMAL DYSPLASIA AND OF ROTHMUND'S SYNDROME

To the Editor:—Cole, Giffen, Simmons and Stroud (The Journal, *Nov. 10, 1945, p. 723) described congenital cataracts* in 2 sisters aged 24 and 10 months with congenital ectodermal dysplasia. Both infants exhibited cataracts in early life and a peculiar skin abnormality. The authors state that "on casual observation the skin changes suggest an exaggerated case of cutis marmorata. On close inspection the skin of most of the body is mottled with dull, red, confluent, slightly depressed and mildly indurated zones, which blanch very slightly with pressure. Between these darker areas are small, pale, ill defined 3-10 mm. islands of skin which appear whitish. These skin changes are most accentuated over the extremities, head and back." This description is identical in detail with the description and the picture published first by Rothmund in 1868 entitled "Cataracts in Association with a Peculiar Degeneration of the Skin" (Rothmund, A.: Ueber Katarakt in Verbindung mit einer eigenthumlichen Hautdegeneration, *Arch. f. Ophth.* **14**:159, 1868, cited by Beetham, W. P.: Atopic Cataracts, *Arch. Ophth.* **24**:21 [July] 1940). This syndrome, known in the literature as "Rothmund's syndrome," occurs collaterally in sisters and brothers in the first weeks or years of life. In the families of infants afflicted with this disease similar abnormalities are suggested only vaguely in 1 or 2 instances. Certainly a dominant or incomplete dominant heredity is not observed in these infants.

In contrast to Rothmund's syndrome, the heredity in ectodermal dysplasia of the anhydrotic type (type Widderburn-Guilford-Hutchinson) is definitely dominant (Thannhauser, S. J.: Hereditary Ectodermal Dysplasia of the Anhydrotic and Hydrotic Types, *Practitioner,* Library of Medicine and Surgery, 1938, New York, Appleton-Century Company, **13**:473). In ectodermal dysplasia of the hydrotic type (type McKay and Davidson) the abnormality is transmitted by both sexes and present in many members of the ancestry. The clinical triad of ectodermal dysplasia of the anhydrotic type consists of (1) anhydrosis, (2) hypotrichosis and (3) anodontia or severe abnormality of the denture. Persons exhibiting ectodermal dysplasia of the hydrotic type maintain the ability to perspire; the sweat and sebaceous glands are present in some instances not as numerous as in normal persons. Similar to the cases of the anhydrotic type, absence of many teeth or anomalies of the denture, as well as dystrophy of the hair, are observed. In these cases of the hydrotic type dystrophy of the nails is an additional feature. None of the numerous cases of ectodermal dysplasia of the anhydrotic and hydrotic type reported in the literature exhibited either cataracts in infancy or later life or abnormalities of the texture of the skin as described by Cole, Giffen, Simmons and Stroud. The skin in cases of ectodermal dysplasia of the hydrotic and anhydrotic type is smooth, fine and dry. S. J. Thannhauser in an article entitled "Werner's Syndrome (Progeria of the Adult) and Rothmund's Syndrome: Two Types of Closely Related Heredofamilial Atrophic Dermatoses with Juvenile Cataracts and Endocrine Features" (*Ann. Int. Med.* **23**:559 [Oct.] 1945) attempted to describe the features of these syndromes and to distinguish the symptomatology of these clinical entities from related clinical syndromes like ectodermal dysplasia of the hydrotic type. According to the analysis of the syndromes discussed in Thannhauser's paper it is evident that the cases of the 2 sisters with infantile cataracts and atrophic hereditary dermatoses are not correctly classified by Cole, Giffen, Simmons and Stroud if listed as ectodermal dysplasia of the hydrotic or anhydrotic type.

The main features of the 2 infant sisters are cataracts and a dermatosis as described by Rothmund. A. Siegrist (Der graue Altasstar, Berlin, Urban and Schwarzenberg, 1928), A. F. Schnyder (Ueber Kataract bei poikilodermie-artiger Hauterkrankung, *Klin. Monatsbl. f. Augenh.*) and more recently by R. Seefelder (Ueber familiäres Auftreten von Kataract und Poikilodermie) collaterally occurring in sisters and brothers of one family. The etiology common to the two syndromes, ectodermal dysplasia of the two types as well as Rothmund's syndrome, are germ plasm defects. In ectodermal dysplasia a defect restricted to the ectodermal germ layer is evident, while in Rothmund's syndrome a multiple germ plasm defect is suggested, since, besides the ectodermal, also the mesodermal layer (involvement of the veins visible as telangiectases and distended veins of the subcutaneous tissue) is involved in the malformation.

In the interest of a correct registration in indexes it would be important that the authors reconsider their classification of the cases of the 2 infant sisters afflicted with cataracts and atrophic dermatoses, particularly because the 2 infant sisters are the first 2 cases of Rothmund's syndrome published in the American literature.

S. J. Thannhauser, M.D., Boston.

ODOROUS WOUNDS AND FISTULAS

To the Editor:—In The Journal, Dec. 15, 1945, page 1094, Dr. W. Wayne Babcock offered several valuable suggestions pertaining to the treatment of odorous wounds and fistulas. As no drug is equally efficient in all instances and complete failures may occur, a few additional methods of dealing with malodorous wounds may be given a trial.

In advanced ulcerative cancer of the breast with offensive odors, granulated sugar scattered over the wound at frequent intervals is of great value.

Where the amount of secretion is large, powdered charcoal may be preferable on account of its great hygroscopic power. As a deodorant, charcoal is particularly efficient in urinary fistulas. Because of the property to absorb urinary odors, charcoal was frequently seen in men's lavatories before it was replaced by modern plumbing installations.

Another economical way of combating fetid secretions consists in applications of sterilized sawdust with addition of 10 per cent iodoform, placed in small gauze sacks. The absorptive and deodorant power of this mixture is especially appreciated by patients with jejunostomy or ileostomy. In chronic conditions this method offers the additional advantage of a very low cost.

It goes without saying that all these methods can be considered only as an adjuvant to an untiring nursing care.

Joseph K. Narat, M.D., Chicago.

Council on Medical Education and Hospitals

At its December 1945 meeting the Council on Medical Education and Hospitals of the American Medical Association passed the following resolution:

The Council on Medical Education and Hospitals of the American Medical Association does not intend to remove any hospital from the lists of hospitals approved for internships or residencies which furnishes teaching facilities to any veteran medical officer who is eligible for educational benefits under the Servicemen's Readjustment Act, provided the veteran is legally eligible for medical licensure in the state in which the hospital is located.

Victor Johnson, Secretary.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Compensability of Traumatic Neurasthenia.—In the course of his employment in 1936 the claimant sustained an injury to his left leg, which necessitated amputation halfway between the knee and the ankle. The Department of Labor and Industries of the state of Washington afforded him treatment, allowance for time lost, made the maximum award possible under the statute then in effect, for permanent partial disability and closed his claim in 1938. In 1941 the claimant petitioned the department to reopen his claim on the ground of aggravation of disability. He alleged that the end of the stump of his leg was tender; that the left knee was painful and unstable and the left thigh was atrophied; that he suffered pain and discomfort in the genitourinary tract, pain in the back, headaches, dizziness, and loss of hearing, vision and memory. The department, in effect, declined to reopen the claim and he appealed to the superior court, Pierce County, where the matter was tried by jury. The jury returned a verdict in favor of the claimant for 60 per cent of the maximum $2,400 allowable under the industrial insurance act of Washington for unspecified permanent partial disability, and the department and the employer appealed to the Supreme Court of Washington.

The sole question for our determination, said the Supreme Court, is whether the evidence adduced in the trial court was sufficient to take the issue of aggravation of disability to the jury. From the evidence it appears that the claimant has developed a well defined case of neurasthenia since his original claim was closed by the department in 1938. At the trial a physician testified that in his opinion this condition is the result of the injury sustained in 1936. The appellants contended, however, that the opinion of this physician is based wholly on subjective symptoms and is therefore insufficient, under applicable decisions of the Supreme Court of Washington, to sustain the award. The substance of the decisions cited by the appellants, answered the court, is that the opinion of the physician, based *wholly* on statements made by a workman, disclosing subjective symptoms only, is insufficient to take the issue of aggravation of disability to the jury. But here the physician testified:

> He can hear a watch tick from 4 to 5 inches but he can't locate the sound, he claims. . . . The measurements of his right thigh at 10 inches is 22, where the left thigh is only 19½. . . . The stump of the left leg is tender and sensitive and there is pain up and in the left groin and the hip. . . . There is some swelling and tenderness through the knee and the stump. . . . There is also a growth about the size of a walnut at the head of the fibula. He is very nervous. . . . It [difference in measurement of the thighs] shows an atrophy of the injured thigh. . . . You can see some of these conditions; others you cannot. Part are subjective and part are objective.

Obviously this physician's opinion is not based *wholly* on subjective symptoms. The appellants contended, however, that the objective symptoms referred to in the physician's testimony all pertained to the condition of the left leg, for the injury to which the claimant was awarded previously the maximum compensation allowable. The trial court, answered the Supreme Court, very properly instructed the jury that, this being the case, no additional allowance for aggravation of disability could be made on account of the condition of the leg. But this did not render evidence of the condition of the leg incompetent. On the contrary, the condition of the leg was very pertinent to the establishment of the neurasthenic condition on which the claim of aggravation of disability must rest. A physician called by the appellants testified in effect that an injury resulting in an amputation frequently does cause an injured workman to have functional complaints; that by functional he meant a condition "more or less imaginative on the part of the person, that is, something that can't be demonstrated on examination and yet the person just feels it himself"; and that the complaints of the workman "outside of the leg" were connected with the accident "from the functional standpoint" solely.

As justifying its conclusion the court quoted from *Peterson v. Department of Labor and Industries*, 178 Washington 15, 33 P. (2d) 650, as follows:

> To say that there has been no aggravation of appellant's injuries since September 1929, we would have to ignore the testimony of several disinterested lay witnesses and two physicians who testified on behalf of appellant. The lay witnesses testified to a pronounced increase in loss of memory. The two medical men found an hysterical condition to exist that was manifestly not feigned. There is no evidence in the record of the existence of such symptoms in 1929. . . .
>
> To say that this progressing disability of appellant is not due to the accident of July 10, 1926 is, in our opinion, contrary to the clear preponderance of the evidence. No other cause for his present condition is suggested. . . . Classifying his case as a "desire neurosis," it is still traumatic in origin. It is real, and it is a condition that would not exist but for the accident.

What was said in the Peterson case, said the court, might well be said of the evidence in this case. The judgment in favor of the claimant was accordingly affirmed.—*Anderson v. Department of Labor and Industries, 159 P. (2d) 397 (Wash., 1945).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Board in Specialties were published in The Journal, Jan. 19, page 173.

BOARDS OF MEDICAL EXAMINERS

Alabama: Mar. 19-21. Sec. Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.

Alaska: Juneau, March 5. Sec., Dr. W. M. Whitehead, Box 140, Juneau.

Arkansas:* *Medical.* Little Rock, June 6-7. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 6. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Written.* Los Angeles, March 11-14. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

Connecticut:* *Medical. Examination.* New Haven, March 12-13. *Endorsement.* New Haven, March 26. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, March 12-13. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

Delaware: *Examination.* Dover, April 9. *Reciprocity.* Dover, April 16. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

District of Columbia:* *Reciprocity.* Washington, March 11. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

Florida:* Jacksonville, June 24-25. Sec., Dr. Harold D. Van Schaik, 2736 S.W. Seventh Ave., Miami 36.

Indiana: Indianapolis, April 25-27. Sec., Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

Kansas: Kansas City, March 12-13. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City 10.

Kentucky: Louisville, March 25-27. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville 2.

Maine: Portland, March 12-13. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

Massachusetts: Boston, March 12-15. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston.

Michigan:* Detroit, March 26-28. Sec., Board of Registration in Medicine. Dr J. E. McIntyre, 100 W. Allegan St., Lansing 8.

Montana: Helena, April 1-3. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

Nevada: *Reciprocity.* Carson City, Feb. 4. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Jersey: Trenton, June 18-19. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico:* Santa Fe, April 8-9. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

New York: Jan. 28-31. Sec., Dr. Jacob L. Lochner, Education Bldg., Albany.

Ohio: *Examination.* Columbus. March 19-22. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma:* Oklahoma City, March 23. Sec., Dr. J. D. Osborn Jr., Frederick.

Pennsylvania: Harrisburg, January. Act. Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

South Carolina: Columbia, Feb. 24-26. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Texas: Austin, March 27-29. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

Vermont: Burlington, March or April 1946. Sec., Dr. F. J. Lawliss, Richford.

Virginia:* Richmond, March 25-28. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke.

Wyoming: Cheyenne, Feb. 4. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Connecticut: Feb. 9. Address State Board of Healing Arts, 250 Church St., New Haven 10.

Florida: Gainesville, June 4. Final date for filing application is May 20. Sec. Dr. J. F. Conn, John B. Stetson University, DeLand.

Oregon: Portland, March 2. Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.

Rhode Island: Providence, Feb. 13. Chief. Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1936 to date. Requests for issues of earlier date cannot be filled. *Requests should be accompanied by stamps* to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Medical Sciences, Philadelphia

210:421-560 (Oct.) 1945

*Studies on Streptomycin in Man: I. Absorption, Distribution, Excretion and Toxicity. H. A. Zintel, H. F. Flippin, Anna C. Nichols, Marjorie M. Wiley and J. E. Rhoads.—p. 421.

Case of Streptococcus Viridans Pneumonia Successfully Treated with Penicillin. S. Solomon.—p. 431.

Observations on Continuous Intramuscular Method of Administering Penicillin. H. L. Hirsh and H. F. Dowling.—p. 435.

Electrocardiographic Observations in Normal Thyroidectomized and Thiourea Treated Rats. R. K. Waller and H. A. Charipper, with technical assistance of A. H. Stenger.—p. 443.

Study of Relationship of Basal Body Temperature to Basal Metabolic Rate in Hospitalized Patients. C. Moses.—p. 453.

*Danger of Continued Arsenotherapy in Cases of Erythema of Ninth Day. W. Leifer.—p. 458.

Possible Effectiveness of L. Casei Factor ("Folic Acid") Concentrates on Refractory Anemia and Leukopenia, with Particular Reference to Leukopénia Following Radiation Therapy. C. J. Watson, W. H. Sebrell, J. L. McKelvey and F. S. Daft, with technical assistance of Violet Hawkinson.—p. 463.

Synchronization of Neurotic Behavior Patterns. E. Bergler.—p. 470.

Atrial Septal Defect: Study of Hemodynamics by Technic of Right Heart Cathéterization. E. S. Brannon, H. S. Weens and J. V. Warren.—p. 480.

Idiopathic (?) Hypoprothrombinemia: Report of Case. V. T. Austin and H. Quastler.—p. 491.

Aplastic Anemia Terminated by Removal of Mediastinal Tumor. G. H. Humphreys and H. Southworth.—p. 501.

Use of Simple Postural Test in Neurocirculatory Asthenia. W. A. Jeffers, S. C. Sheiman and G. H. O'Brasky.—p. 511.

Salmonella Appendicitis. A. D. Rubenstein and B. B. Johnson.—p. 517.

Biologic False Positive Reactions to Tests for Syphilis. H. Beerman.—p. 524.

Cancer of Mouth: Its Present Day Treatment. W. Mayne.—p. 548.

Studies on Streptomycin in Man.—Zintel and his co-workers found that the blood level of streptomycin following a single intravenous injection in man is better maintained than in the case of penicillin. Detectable amounts were usually present for six hours, as compared with two and one-half to three hours in the case of penicillin even when the intramuscular route was used for the latter drug. Following parenteral injection the drug is distributed throughout most body fluids: blood, urine, ascitic fluid, pleural fluid, aqueous humor, vitreous humor, amniotic fluid and bile. Small amounts of the drug appeared in the spinal fluid in healthy persons, but in a case of Hemophilus influenzae meningitis the spinal fluid contained 25 units per cubic centimeter. The main route of excretion for streptomycin after parenteral injection appears to be the urinary tract. Relatively little transfer of streptomycin occurs between the blood and the lumen of the gastrointestinal tract in either direction. Owing to the poor transfer of the drug across the walls of the alimentary tract, it would seem appropriate to use the drug both orally and parenterally in infections in which the pathogenic organisms are found both in the gastrointestinal tract and in the blood stream. Early side reactions have not been alarming, and late toxic effects have not so far been observed.

Danger of Continued Arsenotherapy in Erythema of the Ninth Day.—Leifer reports 14 cases in which prompt resumption of arsenical treatment after reaction was followed by severe parenchymatous injury. All of the patients were soldiers. Oxophenarsine hydrochloride was given twice weekly and bismuth subsalicylate once weekly. The maximal dose of oxophenarsine hydrochloride, 0.06 Gm., was generally employed, although frequently the initial dose was 0.03 or 0.04 Gm. The reaction occurred six to eleven days after the first dose of oxophenarsine hydrochloride. In 6 cases it appeared after three doses of the drug had been administered, in 5 cases after four doses and in 3 cases after five doses. Only 3 of the 14 patients had an eruption. Fever after the initial dose of arsenic is usually a manifestation of the systemic Herxheimer reaction, which is ascribed to massive destruction of treponemes in the circulating blood, with release of their toxins or proteins. It does not recur after subsequent injections. Fever after the second, third or later injection of arsenic must be regarded as evidence of toxic reaction or intercurrent infection. The safest course is to consider any febrile episode (except the Herxheimer reaction), especially in the first three weeks of arsenotherapy, a probable manifestation of sensitivity to arsenic. This is particularly true when the entire syndrome of erythema of the ninth day is present. It appears also to apply with equal force to those cases in which no rash is detected. In all 14 patients early continuation of arsenic after the initial reaction led to serious parenchymatous damage in the form of jaundice and agranulocytosis, with or without nephritis. Twelve of the 14 patients subsequently received an intensive course of penicillin without untoward reactions.

Design for Surgical Convalescence. R. Elman and J. T. Akin Jr.—p 716.

Idiopathic Dilatation of Esophagus.—Scott recognizes four clinical types which probably differ from one another in their etiology. These types are (1) achalasia of the esophagus, (2) true cardiospasm, (3) dilatation associated with a constriction at or just above the cardia and (4) dolichoesophagus. Achalasia is probably the most common type. It usually responds well to dilation. In true cardiospasm the reflex originating focus should be discovered and removed. Cases caused by a partial constricting band near the cardia are few in number but are probably resistant to conservative treatment. Dolichoesophagus, an S shaped lengthening with pooling of esophageal contents at different levels, should probably be operated on as soon as it is recognized. This type is very difficult to control when the dilatation becomes gigantic and is complicated by infection of the esophageal wall. Subdiaphragmatic esophagogastrostomy (of the Finney pyloroplasty type) appears to be the operation of choice in cases of idiopathic dilatation of the esophagus resistant to the usual conservative measures. The symptomatic results of this operation are usually excellent whether or not the dilatation of the esophagus is entirely corrected. The danger of the operation is not excessive when proper precautions are taken After this operation has been employed more extensively, the number of cases for which it is indicated will probably be considerably increased, but it should never replace conservative dilation in the majority of cases

Local Use of Sulfanilamide in Appendicitis.—Mueller compares results obtained in a five year period preceding 1940 with the five year period since 1940 when sulfanilamide was used intraperitoneally in acute appendicitis at the Roosevelt Hospital. Sulfanilamide was applied locally in 320 out of a total of 739 cases of acute appendicitis and its complications The mortality in this group was 0.4 per cent and the postoperative complications were relatively few. In a similar group of cases in the preceding five year period operations were performed in 742 cases, with a mortality of 2 83 per cent and with considerably more complications. No serious toxic effects followed the use of sulfanilamide in the peritoneal cavity. Local use of sulfanilamide is preferable because of the possibility of a high local concentration of the drug in the peritoneal cavity. In cases complicated by abscess or peritonitis penicillin is employed postoperatively in addition to the local use of sulfanilamide. In all doubtful cases drainage should be done. as it was before the use of the sulfonamide drugs.

Traumatic Shock.—Fine and his associates earlier presented evidence that in traumatic shock the capillaries outside areas of injury do not "leak" plasma; the essential pathologic condition is not a disturbed capillary permeability but a disturbed peripheral circulation in which the amount of blood in active circulation is deficient. The therapeutic problem is one of restoring normal velocity and volume flow through capillaries. If after loss of blood replacement is effected early the problem is solved, but if too much time elapses before replacement the damage caused by the loss becomes irreversible. Whether this damage consists in a loss of integrity inherent in the central or peripheral circulatory apparatus per se or is secondary to the failure of an extravascular controlling factor is not known. No explanation for the shock state other than the hemodynamic imbalance was necessary. Tourniquet shock differs from hemorrhagic shock, but the authors show that the increased hematocrit of tourniquet shock is a liability over and above that of volume deficiency and can account for the observed differences between tourniquet shock and hemorrhagic shock. Volume deficiency is by far the greater danger, and its restoration is a more urgent need than is that of normal viscosity. Utilizing hemorrhagic shock and eliminating as far as possible operative manipulations, anesthetics and other forms of trauma, which facilitate the development of irreversibility or otherwise complicate the shock state, the authors studied various agents in every instance only after the shock state was found to be unresponsive to the replacement of all lost blood. The course of events in hemorrhagic shock leading to the development of a state of irreversibility to transfusion is a function of the severity and duration of inadequate capillary flow, with a resulting cumulative adverse effect on the integrity of cellular function in general or on a basic biochemical function in a controlling vital organ such as the liver. In studies on the intermediary metabolism in shock the aim was to discover some point in the process of biochemical disintegration, i. e. failure of completion of a normal biochemical reaction, which would identify the onset of irreversibility. It was found that metabolites, including the amino acids, are catabolized as readily in the irreversible as in the reversible phase of shock, almost as well as in the normal animal, and the increased concentration of these substances in the blood represents an adjustment of metabolic reactions at a new level. The effect of viviperfusion of the liver on the prevention of the development of irreversibility is not due to the removal of toxins or to the provision of protective substances by the donor dog during the shock phase, because the same processes operate in the dog viviperfused via the jugular vein

Glycogen Storage Disease.—According to Bridge and Holt a clinical diagnosis of von Gierke's disease or, as it is commonly called, glycogen disease cannot always be made with precision because the criteria necessary to establish the diagnosis are not clearly defined. The variations in symptoms suggest that more than one disease entity may be included under that name. The authors report 2 cases which belong to the so-called hepatic type of the disease. They believe that this form constitutes a clinical and physiologic entity. The 2 patients, a girl of 15 months and a boy of 5½ years, presented a strikingly similar clinical picture The microscopic appearance of the sections obtained at biopsy were indistinguishable from each other or from pictures published in other reports Both showed a high level of liver glycogen The fat content of the liver in both cases was normal. Observations on liver slices freshly removed at biopsy have shown an abnormal stability of the glycogen, but a satisfactory glycogenolytic response was obtained on admixture with fresh normal liver, confirming previous work that the glycogenolytic enzyme system is defective in this condition Liver slices treated with various enzyme preparations, including phosphorylase and amylase, gave results which were inconclusive as to the nature of the enzyme defect It was demonstrated that liver functions other than glycogenolysis may be affected in this disease, defective prothrombin formation and defective methylation being observed In 1 patient a severe lipemia was present at the age of 2 years, which had almost completely disappeared at the age of 6 years, suggesting that the associated disturbance of fat metabolism may be a self-limited one. An unidentified reducing substance was found, probably belonging to the pentose group, in the urine of 1 of the patients. Particular attention is called to two indirect results of the impaired glycogenolysis;

(a) an abnormal conversion of carbohydrate to fat, demonstrated by respiratory quotient studies, which leads to obesity; (b) impaired nitrogen retention, brought about apparently by excessive gluconeogenesis from protein in the effort to sustain blood sugar, a condition which may interfere with normal growth. The latter condition may be satisfactorily treated by the administration of an extra protein meal at night.

Erythroblastosis Fetalis.—The discrepancy between the relatively large number of marriages of Rh-positive men to Rh-negative women, estimated at about 13 per cent of all marriages, and the low incidence of erythroblastosis, namely about 0.1 to 0.2 per cent of births, demands some explanation. Apparently the presence of the factor in the husband and its absence in the wife are not always sufficient to cause the disease in the child. Among factors which might explain this discrepancy Litchfield mentions (1) possible variations in the permeability of the placenta, (2) that more than one pregnancy may be required to induce an adequate degree of immunization, (3) that the disease may be mild and escape recognition and (4) that men who have inherited the Rh factor from one parent only, that is, heterozygous fathers, do not transmit the Rh factor to all children. Theoretically it would seem that isoimmunization could occur in an Rh-negative child of an Rh-negative father and Rh-positive (heterozygous) mother, but it is assumed that this does not occur, because, as is well known, infants produce antibodies very poorly. Blood specimens for determination of Rh factors should be taken from the mother at the same time as blood for the Wassermann test, usually in the second or third months of pregnancy. Blood smears for erythroblastosis should be taken from the infant at the time of delivery. Patients who are likely to have repeated transfusions should be typed for the Rh factor to avoid immunizing Rh-negative persons by the use of Rh-positive blood. This is especially important in women of childbearing age to avoid the possibility of harming an Rh-positive fetus at a later pregnancy. Wiener and Wexler caution that in hemolytic anemia of the newborn transfusions of blood from the mothers are contraindicated because of the additional antibodies which would be introduced; that the father's Rh-positive blood (or that of any other Rh-positive donor) should not be used because the tissues of the infant contain enough stored antibodies to destroy any additional Rh-positive blood, and that the infant should not nurse, since antibodies may be transmitted through the colostrum and milk. They give blood from group O Rh-negative donors.

Surgical Treatment of Coarctation of Aorta.—Crafoord and Nylin believed that, in patients with congenital isthmic stenosis who already possessed a well developed and satisfactorily functioning collateral system between the large arteries arising central to the coarctation and the arteries in the lower half of the body, they could keep the aorta closed at a point immediately peripheral to the left subclavian artery for a considerable period without causing danger through cutting off the blood flow to organs in the part of the body supplied by arterial blood from arteries peripheral to the aortic stenosis. The relatively poor prognosis in cases of aortic coarctation seemed to be sufficient justification for making an attempt at surgical treatment of these patients. The most important diagnostic sign of coarctation of the aorta is the increased blood pressure in the upper part of the body. Some cases of coarctation show a normal blood pressure in the arms. Every young person with hypertension should be examined for coarctation. Absence of pulsations in the popliteal artery or a lower blood pressure in the legs than in the arms should suggest coarctation. Often collateral pathways form tortuous and dilated arteries which can be seen and can be palpated over the back, especially in the interscapular region or on the lateral part of the chest in the axillas. In most cases the dilated tortuous intercostal arteries cause erosions or notchings of the ribs, which are seen in the x-ray film and, if present, they are a sign of coarctation. The authors describe 2 cases in which the Crafoord operation was performed. In both patients the operation was planned as a trial thoracotomy in order to ascertain whether the aortic wall was in a condition to permit circular suture of the vessel after resection of the stricture. If the wall had shown signs of morbidity or if, after mobilization, it seemed unlikely that the aorta could be made sufficiently mobile to allow coaptation of the resected edges without tension, after the removal of the stricture, the authors would not have continued the operation. However, the operation was completed successfully on both patients and both were in excellent health at a follow-up examination six months later.

Rheumatic Infection.—Scarlet fever or infection with the group A hemolytic streptococcus precedes by several days or longer an attack of rheumatic fever. This preliminary infection, which is designated as phase 1, is followed by a quiescent period, phase 2, which lasts from a few days to several weeks, during which an antigen-antibody reaction seems to occur. This is followed by true active rheumatic fever, phase 3, which results in a heart lesion in about three fourths of the children and in a considerable number of adults. Patients, particularly children, who recover slowly from a throat infection, especially if they are pale, perspire easily and have an evening rise of temperature, elevated white blood cell count, increase in pulse rate or accelerated sedimentation rate probably are in phase 2. It is in the hours before the activation of the streptococcus or the antigen-antibody reaction has occurred that salicylates or sulfonamides may be effective if given in moderately large doses. Although salicylates and sulfonamides are the choice drugs for the prevention of phase 1 lapsing into phase 2, penicillin may prove to be useful for patients who are sensitive to sulfonamides or who have been infected by a sulfonamide resistant organism. There is evidence that penicillin is not beneficial in the treatment of rheumatic fever; it may even be harmful. When chorea develops, phase 1 has passed so that prophylactic measures are then of no avail. From 3 to 10 per cent of patients with uncomplicated chorea develop rheumatic heart disease. Since recurrences are less likely in warm climates, patients who are in the latent stage of the disease should spend at least the first winter following an acute attack in the South and should live the rest of their lives in a warm climate if this can be arranged. Lacking this opportunity, a great deal can be done by warm clothing and avoidance of exposure to dampness, chilling and fatigue.

Encephalitis and Personality.—Greenebaum and his associates report observations on 50 children who were referred to the Child Guidance Home because of behavior disorders and personality difficulties which were found to be causally related to a previous attack of encephalitis. The patients were followed for from three to twenty-five years. The fact that there were 39 males and 11 females seems to indicate that males are more susceptible to this type of behavior and personality disorder than females. The onset of the disease was predominantly early in infancy, the bulk of the cases occurring before the age of 5 years. The onset of the behavior problems and personality changes occurred mostly below the age of 10 years. In the majority of the cases the behavior and personality difficulties appeared immediately after the onset of the disease. The virus type of encephalitis predominated in this series. Neurologic findings (pyramidal, extrapyramidal, ocular) were present in all but 9 cases. Five suffered from grand mal, 2 from petit mal and 4 presented parkinsonism. The intelligence quotient range was from 51 to 118. Only 14 were feebleminded. Of 20 children who were retested, 9 showed no change in the intelligence quotient, 1 improved and 10 deteriorated. The children can be grouped into three categories: those with behavior difficulties, the psychopathic and the psychotic. Only 9 of the 50 patients are at present adjusted.

Volvulus of Megacolon Reduced During Barium Enema Examination. A. Melamed.—p. 392.

Osteoid Osteoma of Bone.—According to Jaffe an osteoid osteoma is a small, oval or roundish, nidus-like benign neoplasm of bone. It consists, in varying proportions, of osteoid trabeculae of newly formed osseous tissue and a substratum of vascularized osteogenic connective tissue. The lesion usually does not exceed a centimeter in its greatest dimension and may lie within the spongiosa (perhaps at or near an articular surface) or against the inner surface of the bone cortex, or even within the cortex. Though the nidus-like focus is the osteoid osteoma per se, the total abnormal area in the affected bone may be large, since there may be a perifocal zone of bone thickening or sclerosis extending for a considerable distance beyond the nidus. The author reviews observations on 62 cases. The condition is found chiefly in males, 42 of the 62 cases being in males and the age in all but 2 being less than 30. The roentgenographic picture of osteoid osteoma has two aspects, manifestation of the nidus or osteoid osteoma proper and that of the reaction which it has incited in the surrounding tissue. The nidus is a small, oval or roundish, relatively radiolucent or (less frequently) radiopaque area, often surrounded by a more or less opaque or dense shadow reflecting the reactively thickened or otherwise altered zone of neighboring bone. While persistent local pain and a sharply localized point of tenderness are useful in the diagnosis, it is the roentgenographic picture that constitutes the most valuable diagnostic guide. Removal of the lesion is followed by prompt and lasting disappearance of the complaints. Complete removal is important, since otherwise there may be recurrences. Five typical case histories are reported and illustrated with roentgenograms and photomicrographs.

Radioactive Sodium as Tracer in Peripheral Vascular Disease.—Smith and Quimby direct attention to the use of artificially radioactive elements as tracers in biologic and physiologic studies. Substances can be tagged by mixing with stable atoms a relatively small number of radioactive ones. The tagged atoms continue to be mingled with the normal ones administered at the same time in the same proportions throughout their whole course through the body except for radioactive decay, which can be allowed for if necessary. Radioactive sodium N_{24} is such an isotope. Following its introduction into the body, its transfer by the blood and its arrival at any part can be observed by the use of a Geiger-Müller counter. The authors injected intravenously a few cubic centimeters of isotonic solution of sodium chloride containing the desired amount of the radioactive isotope and traced the circulation of the blood by following the sodium it carried. Studies of this type have now been carried out on more than 200 patients with peripheral vascular disease. The method provides a simple and objective means of determining the blood supply to an extremity through either the main arteries or the collateral circulation. The observations obtained by this method have been especially helpful in demonstrating the competence of the collateral circulation when the main arteries are partially or totally occluded. The method has been of special value in determining the advisability of persisting in conservative as compared to more radical local surgery, and particularly in determining the site of amputation at which healing might be expected. In this capacity it has justified the clinical attitude that in many cases of amputation for gangrene in peripheral vascular disease the knee joint can be saved. Since no toxic material is injected with the sodium, and the accompanying dose of radiation is considerably less than 1 roentgen for each test, there is no contraindication to its repetition at reasonable intervals. In this manner it serves to follow progress of the disease or to test the efficacy of therapeutic measures.

Solitary Myeloma.—The treatment and prognosis of multiple myeloma are usually regarded as extremely discouraging. In recent years numerous reports of solitary myeloma have appeared, in many of which x-ray therapy judiciously carried out delayed the progress of the disease, produced relief of symptoms and prolonged life. Gootnick says that, among 24 cases of myeloma seen in the University of Chicago Clinics, 2 examples of solitary lesions have been observed, both of which responded excellently to x-ray therapy. These 2 cases, together with 59 similar cases of solitary myeloma collected from the literature, were studied with regard to the duration of life, the effects of x-ray treatment and the course of the disease as compared to that of multiple myeloma. The diagnosis in all these cases had been confirmed by biopsy and microscopic examination. The x-ray appearance is of two main types. One type appears as a cystic, trabeculated lesion closely resembling giant cell tumor. The second is a frankly osteolytic lesion closely resembling metastatic carcinoma. The incidence of the disease was highest in the 50 to 60 year age group, in which 26 cases were found. Males were predominantly affected, accounting for 41 cases. The ilium, femur, humerus and thoracic vertebrae were the sites most frequently involved. Bence Jones protein was found initially in only 10 per cent of the 41 cases tested. X-ray therapy following biopsy or curettage was carried out in 43 cases and appears to be the treatment of choice. It gave relief of pain and prolonged life several years beyond the average for multiple myeloma. The average duration of life in the treated cases followed until death was seven years from the onset of symptoms and three years and a half from the original admission.

Simmonds's Disease.—The patient observed by Cooke, a woman aged 59 with increased fatigue and loss of weight for a period of a year, anorexia and numbness of the fingers since an attack of influenza in 1942, and epigastric pain, had had four pregnancies. At the birth of the last child, when the patient was 32, there was a severe hemorrhage and she was in bed seven weeks because of weakness. After the delivery she did not lactate, and the breasts became very small. Menstruation ceased at age 33. Loss of hair was soon noticed (especially axillary and pubic), and the patient gained weight. There developed sensitivity to cold, becoming more pronounced during the last year. At examination she presented the picture of cachexia. An insulin sensitivity test gave further evidence of a lesion of the anterior hypophysis. Urinary 17-ketosteroid assay added weight to this diagnosis. The patient was given no specific treatment and slowly weakened and died of cachexia and heart failure. Necropsy revealed a general splanchnomicria and an "early" pyloric carcinoma, which was not expected. It is problematic whether this was a coincidence or another result of the pituitary lesion.

Recurrence Rate of Urethral Caruncles.—Malpas reviewed 85 cases of urethral caruncle which had been treated over a period of fifteen years. Excision of the caruncle and of the caruncle bearing area on the posterior lip of the urinary meatus was the procedure adopted in 68 cases. In 22 of these cases the caruncle returned, in 18 instances once, in 2 instances twice, in another three times, in another four times. This seems to indicate that recurrence of a caruncle will follow excision in about one third of the cases so treated. The presence and treatment of an associated lesion such as infection or prolapse did not seem to have any bearing on the incidence of recurrence. The period of recurrence ranged between one and fifteen years, more than half occurring within five years. Recurrence was not seen in any of 15 cases treated by coagulation diathermy. This seems to indicate that coagulation diathermy is a more suitable method than excision. It is possible that the fibrosis following the coagulation inactivates the caruncle bearing area of the posterior meatal lip. An electrocautery was used to burn off the caruncle base after excision in 6 cases, but recurrence occurred in 3 of these. The effect of a cautery apparently is not deep enough to prove effective. Radium was used experimentally in 3 cases. The radiosensitivity of a caruncle is not greater than that of the normal urethral mucosa and as a primary method of treatment it is not advisable, though it has a limited scope in the treatment of recurrent caruncle.

Tuberculous Cavity and Monaldi's Suction Drainage.—Roche believes that Monaldi's closed suction method has a definite though limited place in the treatment of pulmonary tuberculosis. In some large cavities its use will make more certain the success of thoracoplasty and diminish the risk of postoperative spread. Occasionally the treated cavity will close and remain healed. If means can be found to produce permanent occlusion of the draining bronchi, suction drainage will have a wider field of successful application and subsequent thoracoplasty will be avoided in many cases. Its use has provided a clearer understanding of the pathogenesis and healing of cavities.

Cerebral Metastases of Ovarian Struma.—Cerebral metastases of ovarian struma in a woman aged 57 were observed by de Bakay and de Lehoczky. A dermoid cyst containing thyroid tissue was removed from the ovary of the patient. Six to eight years after this operation there appeared indistinct symptoms such as fatigue and a slight gait disturbance; later hyperthyreosis and signs of a supratentorial neoplasm appeared. Mental disturbances appeared at the same time. A gradually developing left side hemiparesis and bilateral papilledema with punctiform hemorrhages were observed in the absence of sensory disturbance. These symptoms suggested a frontoparietal tumor on the right side. When ventriculography was attempted, two incisions in the occipital region revealed a small neoplasm in the occipital bone. It consisted of thyroid tissue and was considered as a metastasis of the previous ovarian struma. This concept was supported by the identical microscopic structure of the ovarian struma and the bone tumor. The case differed from instances presenting the usual syndrome of metastatic brain tumor in that bilateral pyramidal symptoms and impairment of consciousness were observed as late as two weeks prior to death. It is probable that there was another tumor in the right frontoparietal region, a metastasis such as that found in the occipital bone.

*Penicillin in Congenital Syphilis in Infants J Meneghello, J Rosselot and O Undurraga —p 784

Penicillin in Congenital Syphilis.—Meneghello and his collaborators administered penicillin to 3 infants aged 8, 3 and 6 weeks with congenital syphilis The clinical and roentgen diagnosis was verified by the Kahn serologic test. Two of the patients had acute glomerulonephritis with anasarca and venous hypertension. The drug was administered intramuscularly every three hours, with the total dose between 30,000 and 50,000 Oxford units for each kilogram of body weight. Clinical, roentgenologic and serologic cure was obtained in all cases The renal disease also was controlled. Penicillin in adequate doses is harmless and effective in the treatment of congenital syphilis of infants.

Hematology in Tuberculosis.—Birkhaug and Schjelderup report a hematologic study on comparable groups of normal and tuberculin negative guinea pigs immunized with BCG by Rosenthal's multiple puncture, Weill Hallé's scarification and Wallgren's intracutaneous vaccination methods. Fifty-eight days after vaccination, when all the animals had become allergic, all of the vaccinated animals and the control group were inoculated intraperitoneally with 0.0001 mg. of a highly virulent strain of human tubercle bacilli The intracutaneous tuberculin test with 10 mg. of tuberculin was performed on the vaccinated animals and on the control group By comparing the control group tuberculin reactions with the immunized group reactions it appeared that the tuberculous infection developed more slowly in the multiple puncture group, a little more rapidly in the intracutaneous group and still more rapidly in the scarified group. All the surviving animals were killed 103 to 110 days after the inoculation with the virulent strain. The macroscopic scoring of the tuberculous involvement in the vaccinated and in the control animals and the exact quantitative assessment of the volume and weight of the individual organs and glands demonstrated that the multiple puncture group presented the smallest degree of tuberculous lesions, the scarification and intracutaneous groups presented a higher degree, while the control group showed much greater spread of tuberculous lesions than the BCG immunized groups The nonvaccinated and similarly infected control guinea pigs showed that significant abnormal deviations in monocytes, monocyte-lymphocyte ratio and leukocytic index of neutrophils, lymphocytes, monocytes and total white cells register most accurately the advancing tuberculous disease The blood picture in the animals immunized with BCG parenterally and superinfected with virulent tubercle bacilli revealed a significantly retarded abnormal deviation in the monocytes, monocyte-lymphocyte ratio and leukocytic index. The multiple puncture BCG vaccination method, however, produced a slightly more retarded abnormal blood picture than the scarification and intracutaneous BCG vaccination methods In the same group of animals the hematologic study substantiates the pathologic data that parenteral BCG vaccination produces considerable resistance against a virulent tuberculous infection.

Polyneuritis from Sulfanilamide.—Müller reports 7 cases of polyneuritis following chemotherapy in 2 women and 5 men. The patients, who were admitted to the neurologic clinic of the Serafim Hospital in Stockholm, were between the ages of 3 and 56 years. Two of them were treated with sulfanilyldimethylsulfanilamide (uleron), 1 with sulfanilamide, 2 with sulfathiazole, 1 with sulfanilamide, sulfapyridine and sulfathiazole and 1 with sulfapyridine In the cases of polyneuritis caused by sulfanilamide, sulfapyridine and sulfathiazole the symptoms were more extensive and more pronounced than in the cases caused by sulfanilyldimethylsulfanilamide and sulfamethylthiazole. In addition there was less motor disturbance than in polyneuritis caused by sulfanilyldimethylsulfanilamide and sulfamethylthiazole. The incidence of polyneuritis is probably greater after treatment with sulfanilyldimethylsulfanilamide and sulfamethylthiazole than with the administration of other nonmethylated sulfanilamide compounds. The possibility that in some cases polyneuritis may result from a purely toxic damage to the nerve tissues cannot be excluded In general, an allergic reaction seems to be responsible for its occurrence, as polyneuritis may result from serum administration. Previous damage to the nervous system, achylia and thiamine deficiency may be predisposing factors which render the patient susceptible to polyneuritis. Muscular exertion may cause a latent polyneuritis to become manifest To prevent the occurrence of polyneuritis, chemotherapy should be practiced for as short a period as possible. Intermittent administration of the drug should be avoided. Methylated preparations should not be employed. Patients who on the occasion of previous treatment presented signs of hypersensitivity such as drug fever or exanthems should be desensitized before repeating chemotherapy. Polyneuritis due to sulfonamide administration suggests that further chemotherapy should not be employed

Diaphragm Contractions Synchronizing with Heart Movements N. Söderström —p 95

Toxic Diffuse Goiter After Thyroid Treatment.—Bruun reports 18 cases of thyrotoxicosis developing in patients who were receiving thyroid preparations In the same period a total of 485 patients were treated for thyrotoxicosis. It appears therefore that patients with thyrotoxicosis due to thyroid therapy represent 3.7 per cent of the total number of patients with this condition All the 18 patients were women, 10 of them in the climacteric age group In 11 of the 18 cases the thyroid treatment was instituted for simple obesity. Three of the 18 patients showed a familial disposition to toxic diffuse goiter since among their nearest relatives unquestionable instances of this condition were ascertained Two of the 18 patients had a simple goiter prior to the thyroid treatment, and 3 had hypothyroidism. Thus, disposition to thyroid disease could be demonstrated in 8 patients. Pronounced unilateral exophthalmos was found in 4 patients Since this symptom has been described also in 3 of the previously reported 28 cases of toxic diffuse goiter after thyroid therapy, pronounced unilateral exophthalmos in patients with thyrotoxicosis should raise suspicion of a preceding treatment with thyroid substance. In Denmark the yearly consumption of thyroid preparations amounts to 6,600,000 tablets (1 tablet = 100 thyroid units). This is calculated roughly to be at least five times greater than the amount required by the myxedema patients living in this country. The greater part of the thyroid preparations is probably consumed by other patients, chiefly by those with obesity. Thyroid therapy in obesity always entails a certain risk and is therefore once more condemned

Book Notices

A Primer of Electrocardiography. By George Burch, M.D., F.A.C.P., Associate Professor of Medicine, Tulane University School of Medicine, New Orleans, Louisiana, and Travis Winsor, M.D., Instructor in Medicine, Tulane University School of Medicine. Cloth. Price, $3.50. Pp. 215, with 235 illustrations. Philadelphia: Lea & Febiger, 1945.

This book differs from other recently published books on electrocardiography in that it is more concerned with the basic principles and concepts of electrocardiographic interpretation than with exhaustive description of empirical findings. If used in conjunction with other monographs on the subject, as the authors recommend, it will fulfil its purpose and offer the reader a concise outline of the theory of electrocardiography, mainly as formulated by F. N. Wilson and his co-workers and elaborated by Richard Ashman, R. H. Bailey and their co-workers. The more recent contributions of these authors, like those dealing with the ventricular gradient, are incorporated.

The particular approach of the authors may explain why certain problems are not dealt with although they are of utmost practical importance; thus the variety of the patterns of left heart strain is not discussed and the importance of the chest leads for the diagnosis of left heart strain is neither stressed nor illustrated. We cannot agree with the statement that the electrocardiographic picture of acute massive pulmonary embolism lasts only a few hours; in our experience the changes may persist for many days or even weeks. The misleading terms of complete, incomplete and partial bundle branch block, if used, should be defined as being purely electrocardiographic and not anatomic or physiologic. Exception can be taken to the presentation of some problems in the chapter on disorders of the heart beat. No mention is made of the importance of excluding nonconducted auricular premature systoles before diagnosing sinoauricular block. The authors do not mention that in sinoauricular block the pause may be less than two normal cycles. They discuss ventricular escape but do not mention nodal escape with aberrant ventricular conduction; the only kind of septal premature beats that can be diagnosed, namely those occurring in the presence of bundle branch block, is not mentioned. A number of conditions other than premature beats and auriculoventricular block responsible for bigeminal rhythm are not discussed. In describing parasystole the authors fail to name its principal feature, the varying coupling of the premature beats. The mechanism of dissociation is not sufficiently explained; nothing is said about its occurrence in the presence of partial block.

The importance of multiple chest leads for the recognition of myocardial infarction is well demonstrated and we can fully subscribe to the statement that "there is a greater need to take the term exploring electrode literally and really to explore the various regions of the heart in order to locate precisely the site of infarction and to estimate its size."

Essentials of Histology. By Margaret M. Hoskins, Ph.D., and Gerrit Bevelander, Ph.D. Cloth. Price, $3.50. Pp. 240, with 137 illustrations. St. Louis: C. V. Mosby Company, 1945.

This book was originally published as Hoskins and Bevelander's *Outline of Histology*. Its purpose is to describe for the student the most important morphologic characteristics of the tissues and organs, leaving to the individual teacher the task of building on this foundation "such superstructure of detail and theoretical material as the conditions of his course permit." The result is simply an enumeration of morphologic data. Lacking are the functional correlations and developmental relationships which make the material come to life. Whether or not such a book fulfils a need depends on the character of the course in histology. In general, for medical students, more will be required. Certain improvements have been made in the original Outline of Histology. The illustrations are better and are labeled in more detail; several new ones have been added. The section on dental histology, which constituted the whole second part of the outline, has been much shortened. The present work includes new sections on the brain and on the general sense organs, and a separate chapter on glands. Not many teachers in American medical schools will be satisfied that this book contains the "essentials of histology."

The Cerebrospinal Fluid Total Protein in the Psychoses. Studies from the Central State Hospital, Indianapolis, Indiana. Vol. 10. Max A. Bahr, M.D., Superintendent. Walter L. Bruetsch, M.D., Clinical Director. [Collected Reprints.] Cloth. Various pagination. Indianapolis, Indiana: Central State Hospital, 1942.

This is not a real monograph. Three papers, one by Bruetsch, Bahr, Dieter and Skobba, the other by Bruetsch, Bahr, Skobba and Dieter and a book review by Bruetsch have been bound together. These papers are all related to the subject indicated by the title. The contents of the first two papers are rather repetitious and the book review has little bearing on the question. The only value of the contribution is that a systematic report on the spinal fluid findings of all the patients newly admitted to the Central State Hospital has been made. This included 2,823 examinations and excludes the syphilitic psychoses. The patients were admitted during a ten year period from 1930 to 1940. An increase in the spinal fluid protein was found in 5 per cent of the male and 3.2 per cent of the female patients suffering from dementia precox, 5.2 and 3.8 per cent respectively of the manic-depressive group, 4.9 and 4.7 per cent of the involutional psychoses, 25.4 and 16.2 per cent of the cerebral arteriosclerotic and finally 12.7 and 2.9 per cent of the senile psychotic. The theory of the reasons for these findings is discussed in some detail but no strikingly new conclusions are reached. The work conceivably would have more weight and be more convincing had a comparison been made between the findings in these and in 3,000 normal persons. It is factual that the Pandy test and the total protein may easily be misinterpreted, because even a normal spinal fluid may seem to show an increase in protein. This may be due to the manner in which the spinal puncture is performed. If the needle is inserted too far and the venous plexus on the anterior wall of the spinal canal is irritated, an increase of protein may result. This is not a matter of disease but rather a result of the method of obtaining the fluid. Psychotic men are generally much more resistive than psychotic women. Perhaps this explains the striking difference in the findings between the sexes.

Fractures & Orthopaedic Surgery for Nurses and Masseuses. By Arthur Naylor, Ch.M., M.B., M.Sc., Resident Surgical Officer, Westwood E. M. S. Hospital, Bradford, England. Foreword by Ernest Finch, M.D., M.S., F.R.C.S., Professor of Surgery, University of Sheffield, Sheffield, England. Cloth. Price, $5. Pp. 288, with 243 illustrations. Baltimore: William Wood & Company, 1945.

The author has written this book to help those who devote themselves to the nursing of traumatic and orthopedic cases. The success of orthopedic surgery is dependent on the knowledge, skill and care of the nurses and physical therapists to whom after-care and treatment is delegated. With the present crowded curriculum, the student nurse has often only a bare minimum of instruction in orthopedic surgery. In spite of this about one fifth of her surgical work will be concerned with this specialty. This book is written to show the nurse how the principles are applied in orthopedic surgery and as a supplement to her lectures in surgery. The author emphasizes the three essentials of treatment, prevention of deformity, correction of deformity and maintenance of correction; "the greatest of these" is prevention.

Orthopedic surgery must be distinguished from cults such as osteopathy and chiropractic surgery. Osteopathy is based on the theory that structural defects of the body are the predisposing cause of disease, and treatment is directed primarily to the rectification of these by manipulative methods. It must be added, however, that no one has demonstrated the alleged structural defect or subluxation either by roentgenograms or at postmortem examination. Chiropractic treatment postulates that displacements of the vertebrae produce pressure on the nerves and prevent the free flow of the "nerve force" which is essential for the well-being of the body. These "displacements" are corrected by manipulation without anesthesia. Again, radiology and pathology fail to substantiate the presence of the alleged lesions.

Operative measures should be regarded as incidents and not as the essential part of a long-term plan of treatment, while attention to minute details is essential to a successful outcome. Rehabilitation is the mechanism of placing the patient in a position to pursue his former or equivalent occupation by means of surgery, nursing, physical therapy and psychologic treatment and requires cooperation between surgeon, nurse, masseuse, patient and employer. The book contains chapters on orthopedic apparatus, operating room technic, methods of correction of deformity, amputations, fractures and dislocations, diseases of bones and joints, diseases of joints, disorders of the soft tissues, congenital deformities, disorders of the epiphyses, peripheral vascular lesions, paralyses and disorders of the spine and foot.

Careers in Safety: Choosing a Vocation in the Field of Accident Prevention. By Herbert J. Stack, Ph.D., Director, Charles C. Hawkins, Ph.D., Research Associate, and Walter A. Cutter, Ph.D., Administrative Assistant, Center for Safety Education, New York University, New York. Kitson Careers Series, edited by Harry D. Kitson, Ph.D. Cloth. Price, $1.50. Pp. 152. New York & London: Funk and Wagnalls Company, 1945.

This book is useful in vocational guidance. It describes the work of promoting safety and discusses in some detail the work of the safety engineer, control of automobile traffic, principles in safety education, industrial hygiene and occupational diseases, principles in private safety organizations and in the insurance business, working with government agencies and accident prevention in the armed forces. It has a chapter on getting along with people and a closing chapter somewhat in the nature of a sales talk which deals with the challenge of careers in safety. There is an index to jobs in safety which refers back to the preceding context and does not, as might be supposed, actually list jobs. The book is documented with references for the several chapters. For the vocational counselor this should be an interesting and worth while production.

The Dietary of Health and Disease. By Gertrude I. Thomas, Assistant Professor of Dietetics, University of Minnesota, Minneapolis, Minn. Fourth edition. Cloth. Price, $3.50. Pp. 308, with 10 illustrations. Philadelphia: Lea & Febiger, 1945.

The fourth edition of this textbook on nutrition for nurses includes the most recent scientific contributions in this field, particularly in the rapidly developing work on vitamin and protein nutrition. The author gives sufficient information on each subject to provide the reader with a substantial understanding but does not burden with details. Perhaps for this reason an unusually extensive coverage of the many topics related to preventive and therapeutic nutrition could be made. The style of presentation is on a high scientific level, with discussion supported by facts and figures. The number of recipes given is excessive for a textbook, however. The arrangement of the material may be open to some criticism, since a better separation might have been made under the headings of fundamentals, foods and dietary management of the sick. The information given under all chapters is aimed at being practical. Under discussion of vitamins a commendably clear distinction is made between those of proved value in human as compared to animal nutrition. In general only the highlights of special dietetic therapy are given, as should be in a book of this type, although the details for the diabetic regimen are rather extensive. The information given for diet in skin conditions could well be omitted. The volume can readily be recommended as a reliable nutrition textbook for nurses, particularly as one of lasting usefulness because of the practical information and numerous tables contained in it.

Everyday Psychiatry: Concise, Clinical, Practical. By John D. Campbell, M.D., Commander, M.C., U.S.N.R. Designed for Practitioners and Students. Fabrikoid. Price, $6. Pp. 333. Philadelphia, London & Montreal: J. B. Lippincott Company, 1945.

The author sets out to present psychiatry to practicing physicians, medical students and social workers through a systematic approach of borderline mental conditions which constitute the bulk of every specialist's practice rather than by lengthy accounts of the rarer and relatively hopeless psychotic. But on page 3 he explodes the following bomb: "The essence of this work is that human nature expresses itself through four basic personality traits and two secondary personality factors. Environment, which has been overemphasized in psychiatry, is the medium in which the basic personality factors react. These traits are inherited, constitutional and immutable and are not subject to change by environment, education or training. The four basic personality factors are intelligence, conscience, emotional reaction and psychosexual development." Then "Secondary to these four basic personality attributes are two other factors which are not directly inherited and constitutional but develop as a corollary of, or as a compensation for, any deficiency or overdevelopment of the basic traits. These secondary characteristics are sociability and special modes of adjustment." Later the author juggles intelligence, conscience, emotional stability and psychosexual development in percentages to indicate the various innumerable potential personality types as the basic traits combined in infinite permutations. The resultant personality type is immutable. Such are the basic concepts from which our general practitioners are to understand the everyday problems of human nature in health and sickness! A more reactionary backward basis in these days of progressive dynamic psychiatry cannot be conceived. This book is a powerful example of the difficulty in creating badly needed psychiatric knowledge among medical students and doctors. The articulate members of the psychiatric speciality plunge backward; those who have much to offer are too busy doing research, teaching and caring for patients to write the sorely needed textbooks.

Organic Chemistry with Applications to Pharmacy and Medicine. By Eldin V. Lynn, Ph.D., Professor of Chemistry, Massachusetts College of Pharmacy, Boston. Second edition. Cloth. Price, $4.50. Pp. 355. Philadelphia: Lea & Febiger, 1945.

This textbook follows the traditional plan of organization but, in addition, includes discussion of special compounds of interest to pharmacy and medicine and emphasizes those usually discussed by the abbreviations U. S. P., N. F. or N. N. R. Although the book adequately fulfils its special function in applying organic chemistry to pharmacy, it leaves much to be desired as a textbook of organic chemistry for premedical students when compared with other recent volumes, for numerous opportunities to relate organic materials to medicine are neglected. Mention of the relation of compounds and reactions to specific roles in medicine or metabolism are unfortunately omitted in many cases. Vitamins are discussed in various sections rather than as a group of compounds of importance to organisms. The questions at the end of each chapter are a desirable supplement. However, one desirable feature of brief textbooks, the inclusion of supplementary references to other books and the current literature, is confined to only one page at the end of the book. Conditions of a reaction so important in organic chemistry would be better emphasized if the chemical equations included one or two of the more important conditions as is done in other textbooks.

Our Inner Conflicts: A Constructive Theory of Neurosis. By Karen Horney, M.D. Cloth. Price, $3. Pp. 250. New York: W. W. Norton & Company, Inc., 1945.

The physician who has of recent years become more and more aware of the importance of psychopathology in medicine is bound to have been impressed with the fact that the extremist of the anatomic wing has little to contribute to psychopathology. He must also have felt that it is the anthropologist, the sociologist, the psychologist and the biologist who have the most influence on psychiatry and that the descriptive, impressionistic approach to medicopsychologic problems has seen its day. There is a great deal that is interesting, sparkling and philosophically even inspiring in many a page of Jung, Adler, Wilhelm Reich or Karen Horney but there is little that the psychologic therapist can actually learn from them. Karen Horney's latest contribution to her divergences from Freud, like her previous ones, is written with emphasis and serenity, if not clarity; it makes pleasant reading but it reveals little of the psychobiologic nature of man and of the ways and means to treat and influence that which is psychopathologic.

Heintz. By Alan Lake Chidsey. Cloth. Price, $1. Pp. 155, with illustrations by F. Moylan Fitts. Kingsport, Tennessee: Southern Publishers, Inc., 1945.

In every way the desk soldiers get a pretty thorough going over by the humorists. Heintz did his service in the War Department. Col. Francis M. Fitts, who provides the illustrations, worked with the author; together they found a good deal of fun in the job of soldiering in Washington. Physicians who have met Dr. Fitts in his conduct of the medical aspects of the Army Specialized Training Program know that he brings to the project a considerable artistic talent, and they will enjoy this book.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ADMINISTRATION OF IRON BY PARENTERAL INJECTION

To the Editor:—In the June 1, 1940 issue of The Journal, in an article on the therapy of anemia, page 2207, it is stated that iron by injection is useless and even toxic. Several years before I discontinued the use of iron by the parenteral route in hypochromic anemia, preferring liver extract when it became available. In *Hospitalstidende* (May 19, 1944, p. 927) Sven Dahl comments favorably on the effectiveness of iron intravenously as well as intramuscularly. Would you explain this apparent paradox?

W. A. W. Switzer, M.D., Ridgway, Pa.

ANSWER.—There can be no doubt about the fact that parenterally administered iron is therapeutically effective in the treatment of hypochromic anemias. Available evidence indicates that all of the injected iron is utilized by these patients and converted into hemoglobin. At the same same time the parenteral administration if iron is not practical because it frequently is attended by severe toxic reactions.

The toxic manifestations include nasal stuffiness, edema of the face and tongue, inflammation of the conjunctivas with blurring of vision, paresthesias, palpitation, nausea, vomiting, transient fall in blood pressure often to an alarming degree, chills and fever, and a profound sense of weakness. Frequently the vein into which injection is made becomes thrombosed. Goetsch, Moore and Minnich (*Blood*, January 1946) describe these reactions in considerable detail; they used colloidal ferric hydroxide or colloidal ferric oxide for their studies. The severity of the toxic manifestations was dependent to some degree on the amount of iron given and the speed of injection; but some patients experienced undesirable effects after only 15 or 20 mg. Similar but milder reactions were observed by Heath, Strauss and Castle (*J. Clin. Investigation* **11:**1293 [Nov.] 1932) following the intramuscular injection of 6 to 32 mg. of iron as iron citrate green. Ferrous ascorbate may possibly be better tolerated than are the other preparations mentioned, but it too produces toxic changes when administered in large enough doses to be therapeutically effective.

The following calculations serve to illustrate how much iron must be injected to correct an anemia: This is often not appreciated. If a woman with hypochromic anemia has an initial hemoglobin level of 8 Gm. per hundred cubic centimeters and it is assumed that her normal hemoglobin value is 13 Gm., then her hemoglobin must be increased by 5 Gm. per hundred cubic centimeters of blood. If her total circulating blood volume, furthermore, is assumed to be 5,000 cc., there must be a total increase of 250 Gm. of circulating hemoglobin. Since hemoglobin contains approximately 0.334 per cent of iron, 835 mg. of iron is necessary to bring about this much hemoglobin formation. Twenty-four injections would be required if 30 mg. of elemental iron should be given at each administration. Goetsch and her associates did succeed in giving this total amount of iron (as much as 1,400 mg.) at one single injection by intravenous drip to patients with hypochromic anemia. Dramatic reticulocyte responses were obtained and the rate of hemoglobin regeneration was as rapid as 0.27 Gm. per hundred cubic centimeters daily, but the reactions were so severe as to be alarming and in several patients the systolic blood pressure fell as low as 50 mm. of mercury.

It is conceded that an occasional patient cannot tolerate iron salts by mouth. This is particularly true for persons with ulcerative colitis or for patients on whom a colostomy or ileostomy has been performed. Under these circumstances, however, iron may safely be given by transfusion. Until less toxic iron preparations are found for parenteral injection, it is certainly true in general that transfusion is the safest and best way to administer iron parenterally.

THE BLOOD OF GORILLAS

To the Editor:—In a recent fiction magazine there was an article which stated that gorilla blood has the same types as human blood. How closely does gorilla blood resemble that of man?

M.D., Pennsylvania.

ANSWER.—There has been only one complete study of the blood group factors in gorillas (Wiener, A. S.; Candela, P. B., and Goss, L. J.: Blood Group Factors in the Blood, Organs and ctions of Primates, *J. Immunol.* **45:**229 [Nov.] 1942), and this showed that the blood of gorillas differs in many respects from human blood. This study was limited to two live gorillas and one dead gorilla; saliva was obtained from all three, blood only from the dead gorilla—for obvious reasons. There are species specific differences between gorilla blood and human blood, so that human serum may contain natural heteroagglutinins capable of clumping gorilla blood, and vice versa. With regard to the blood groups, the red cells of the gorilla tested failed to clump in either anti-A or anti-B serum, but the gorilla serum contained only anti-A and not anti-B agglutinins. The reason for this apparent paradox was revealed by tests on the saliva, which showed the presence of B-like antigens. Apparently, the gorillas tested all belonged to group B, but the B factor was present in appreciable amounts only in the organs and secretions and not in the red cells. In subsequent tests on urine from fifteen gorillas (Candela, P. B., cited by Wiener, A. S.: Blood Groups and Transfusion, ed. 3, Springfield, Ill., Charles C Thomas, 1943, p. 334) it was found that thirteen lowland gorillas all belonged to group B, while two mountain gorillas both belonged to group A.

TOXICITY OF DDT

To the Editor:—Have any symptoms been reported in workers engaged in the manufacture and/or use of DDT? What precautions, if any, should be taken when DDT is used about the home? What is the treatment, if any, for DDT intoxication?

A. Harry Roller, M.D., Bristol, Vt.

ANSWER.—A case of DDT poisoning in a laboratory worker was described recently by V. B. Wigglesworth. The symptoms of DDT poisoning are (1) an acute neurologic syndrome characterized by hyperexcitability, generalized tremors and convulsions and (2) chronic injury to the liver. These have been described in experimental animals. DDT is absorbed by all routes of administration, including cutaneous absorption if applied in lipoid solvents. Analysis of the urine for organic chlorine as described by Smith or by the colorimetric method of Schechter and Haller in suspected cases of poisoning is of diagnostic value. Gastric lavage, saline cathartics to hasten elimination, and urethane, diphenylhydantoin sodium or phenobarbital to control the neurologic symptoms in acute poisoning are indicated. References:

CIRCUMCISION

To the Editor:—What advantages if any are there in circumcision of the newborn? It seems to me that many more circumcisions are being done than are necessary. I have noticed that if these so-called "tight foreskins" are left alone they seem to be all right when the babies are about 7 months old.

Guy C. Pesce, M.D., Watertown, Mass.

ANSWER.—The advantage of circumcision in the newborn is that it prevents the occurrence of many penile disturbances in later life, such as phimosis, paraphimosis and persistent balanoposthitis. In many hospitals circumcision is done almost as a routine procedure and it may be that many foreskins are needlessly sacrificed. It is a debatable question whether tight foreskins which are left alone do not cause any further disturbance.

EFFECT OF X-RAYS ON HYPERHIDROSIS

To the Editor:—In Queries and Minor Notes in The Journal, Nov. 10, 1945, page 776, an inquirer concerning the value of x-ray therapy in hyperhidrosis was told that "the amount of x-ray therapy needed to control hyperhidrosis of the palms and soles is relatively large. The skin is probably damaged by it. When successful, there is often abnormal drying and changes more or less characteristic of a radiodermatitis. The latter may not appear until years later. This should be enough to decide against x-ray therapy. Dr. Joseph J. Eller and I agreed that the answer is erroneous and should be rectified because it may without good reason deter physicians from the use of x-rays in that condition. We are just preparing a paper on x-ray therapy in hyperhidrosis based on over 500 cases treated in the last twenty years. Our results indicate that, if properly given, x-ray therapy assures a beneficial effect on hyperhidrosis without causing any appreciable damage to the skin.

OVERTREATMENT DERMATITIS OF THE FEET

G. B. UNDERWOOD, M.D.; L. EDWARD GAUL, M.D.
EILEEN COLLINS and MABLE MOSBY
Evansville, Ind.

The human foot has become the target of unbelievable chemical abuse. Feet are seen daily, painted all the colors of the rainbow or daubed so thick with salves that removal with a tongue blade is necessary to view the underlying dermatitis. The shoes smell of solution of formaldehyde and are caked on the inside with fungicidal powders. The patients, when questioned about the number of remedies used, shrug their shoulders and exclaim "I couldn't begin to recall. I've used everything. You are the sixth or seventh doctor I have seen. I've had this stuff between my toes for years. Just when I think it is well, it's back again. Each time it comes back I try something else. I've spent a small fortune for remedies, and look at my poor feet." These patients are sure of the cause of their dermatitis. It is the "athlete's foot" or the "fungus." Lay periodicals teach self diagnosis and treatment.

Every channel of advertising implores the sufferers, directly or by more discreet ways, to apply this remedy or try this when others fail: to put your fungus to sleep; to stop fierce, torturing, maddening itch; to relieve and quiet the burning; to sooth stinging; to heal ugly cracks and to allay suffering and pain. A few of the admonitions to daub dermatitis pedis are displayed in figure 1. When the lay diagnosis has been made, the person can choose for treatment in this locality any of the remedies shown in figure 2. Depending on the one chosen, the advent of overtreatment will be short or delayed.

THE PAST TREATMENT PATCH TEST

To date over 400 dermatologic patients have been patch tested with the remedies applied before the initial visit. These included the assortments of tinctures, lotions, salves and powders. The average number of preparations used in each case was four, but if the dermatitis was recurrent or of long duration the number would exceed ten, even twenty or more. About half of all the remedies tested were prescriptions of proprietaries. In this series 40 per cent of the patients (160) showed positive reactions to one or more of the remedies used. In 35 per cent (56 cases) the remedies had been used in the therapy of dermatitis pedis. As the number of remedies applied increased, so did the incidence of positive reactions. Any patient who shopped long enough would sooner or later apply a salve, tincture, lotion or powder that would contain an irritant or sensitizer.

DERMATITIS CONTACT FROM THERAPEUTIC CHEMICALS

The offender in 35 per cent of the patients (56) was one of the organic mercurials. The contact in 39 was the feet and in 17 other cutaneous locations. Merthiolate was responsible for 90 per cent of the reactions. Phenol was the cause in 14 per cent (22 cases). The feet were the contact in 10 cases and other cutaneous areas in the remaining 12. Ethyl aminobenzoate (benzocaine) caused reactions in 8 per cent (12 cases). In 6 of these the contact was the feet and in the remaining 6 cases other areas of the body. In the remaining 43 per cent (69 cases) the tars and derivatives were the offenders.

The organic mercurials, phenol and ethyl aminobenzoate caused 2 to 4 plus reactions. The latter was characteristic of the mercurials. The sulfonamides were frequently suspected, but positive reactions were not obtained. The tars and derivatives are now being studied. The reactions obtained were usually 1 plus, and about one third of these showed a fine vesiculation. This type of reaction was found in those patients who had used therapeutic tars for a long time or had had contact with industrial tars, oils and distillates. Sunlight can activate a patch test site weeks later into a pruritic, vesicular dermatitis, which involutes slowly. It seems that the therapeutic tars are going to behave on the skin as their close chemical relatives have behaved in industry: a cause of acute and chronic dermatitis. Sollmann[1] dismisses the tars as irritants. From present indications the word "sensitizer" might also be added. Perhaps the quip that skin patients are never ill and never get well may have in the latter an unrecognized truth—therapeutic chemicals inducing recurrences and chronicity in dermatoses. Lane[2] found tar, mercury, iodine, salicylic acid and cresol compounds as frequent causes of therapeutic dermatitis. In a series of 50 cases he found that 70 per cent were due to sulfonamides, 10 per cent to mercury, 10 per cent to unknown agents and the remaining 10 per cent to other drugs. In another series of 125 cases he found that 35 per cent were caused by sulfonamides and 45 per cent by unidentified therapeutic agents. It is believed that the high incidence of reactions to mercury in this locality is explainable on the basis of the extent of use. Merthiolate is applied to dermatologic lesions ranging from insect bites to neoplasms. Its use in the hospital, especially in surgery, amounts to almost bathing in it.

DERMATITIS CONTACT, MERCURY SENSITIZATION

During the first week of this study [3] a patch test with a burn ointment produced a bullous lesion at the testing site and a palm sized flare of patchy erythema around the patch testing adhesive. The follicular involvement was well defined, and similar lesions appeared simultaneously on the other arm and also over the anterior part of the thorax. On repatch testing with each chemical in the remedy, the sample containing the organic mercurial reproduced the aforementioned observations. The mercurials have been the only therapeutic chemicals encountered so far that can produce reactions of this type. They are thus considered "sensitizers" of high index because bullous reactions were obtained in dilutions of 1:1,000,000 with either organic or inorganic mercurials. The determining factor in these cases for positive reactions to the various mercurials and their respective dilutions has been the degree of sensitization. A highly sensitized person will react to organic and inorganic compounds, a low sensitized person will react say to aqueous merthiolate 1:5,000 but not to the tincture, mercuric chloride, metaphen, mercurochrome or ammoniated mercury.

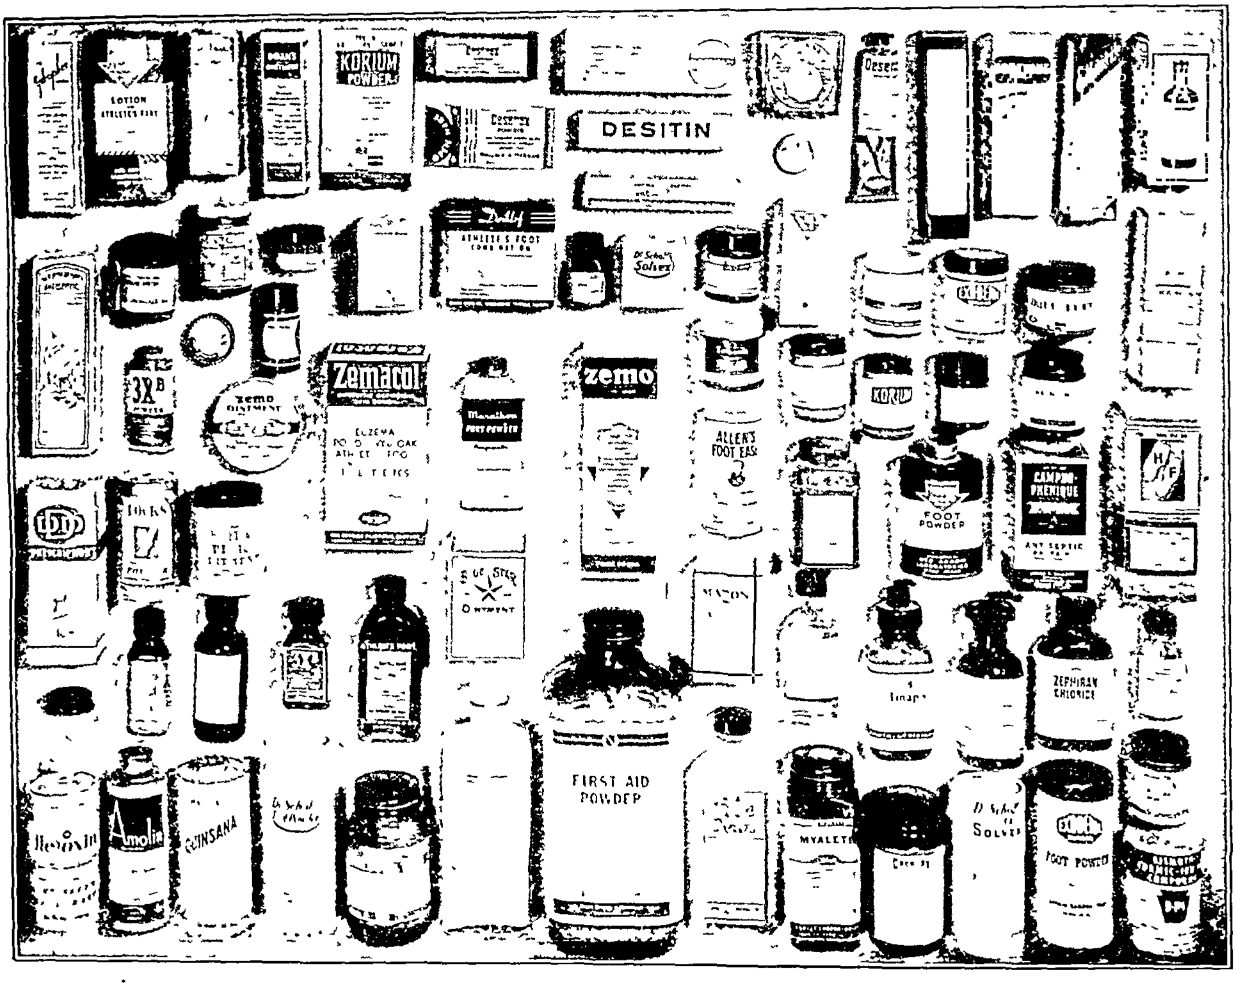

Fig. 2.—Remedies available in this locality for self treatment of dermatitis pedis

The history in every case of a positive patch test to a mercurial in a remedy revealed a previous exposure: mercurial therapy of skin diseases, mercury antiseptics during surgery or delivery at the hospital, the painting of cuts, scratches and minor burns with mercury antiseptics.

The tissue reactions of sensitization are observed most commonly on the hand, forearm, feet and legs. An area of dermatitis or injury is treated with a mercurial. During the next three to five days, healing or involution *seems to be progressing.* Suddenly a ring of erythema appears, followed by edema and soon the wound gapes, the base is pushed to the surface, a creamy pus exudes or the area of dermatitis shows an exacerbation with weeping and spreading. Usually these reactions are looked on as "infection" and more of the mercurial is applied, or something else is tried which may also contain mercury. If another mercurial is applied, in a few days there *is apt to be noted a fine, vesicular,* faintly erythematous dermatitis spreading peripherally from the site of injury or dermatitis. The vesicles may become bullae and the surrounding dermatitis hemorrhagic.

This type of dermatitis involutes slowly, and the initial lesion takes weeks to heal. The extent of the skin sensitization and the severity are determined by future mercury contacts. The sensitization seems to affect primarily the hair follicles and the sweat glands. Dermatitis contact from mercurials has been observed from potassium mercuric iodide,[4] mercurochrome,[5] mercurophen,[6] amalgam filling,[7] cinnabar,[8] ammoniated mercury,[9] merthiolate,[10] phenylmercuric nitrate,[11] yellow mercuric oxide,[12] metaphen [13] and mercury bichloride. The different mercurials inducing dermatitis would seem to indicate that in the mercury ion resides the sensitization properties. The mercury ion plus the tissue reaction—erythema, edema, vesiculation and especially exudation—seem to be a requisite for sensitization. The intensity of the tissue sensitization reaction seems to parallel the index of sensitization. Those patients showing an intense local reaction—appreciable edema, bullae, pustules and hemorrhage—usually reacted to high dilutions of organic and inorganic mercurials. A mercurial patch test (forty-eight hours) can become suddenly positive after as long as a month.

A "WARNING" ON TOPICAL MERCURIALS

In an earlier report [3] it was suggested that all preparations containing mercury designed for cutaneous application carry a "warning" on the label of the presence of a sensitizing chemical. The observations over the past year further confirm the importance of such a warning. The normal skin is apparently well equipped to withstand mercury contacts. An injured skin or skin shorn of its protective layers, particularly a skin already inflamed by contactants, is favorable soil for mercury to induce sensitization. Many of the patients in this series had used a mercurial on an existing contact dermatitis. Vehicles that alter the normal p_H of the skin or affect the lipoid coating or damage the horny layer or chemicals carried by the vehicles that effect similar changes or react with mercury may enhance the sensitization reaction. When Sulzberger [14] added salicylic acid 5 per cent to ammoniated mercury 5 per cent, 50 per cent of the patients tested showed positive reactions, whereas salicylic acid 10 per cent in petrolatum and ammoniated mercury 10 per cent in petrolatum rarely produced reactions. Dermatitis from mercury can be a disabling skin disease, the chronicity may be great and the hazard seems constantly present that renewed contacts will produce increasingly severe recurrences. Physicians, hospitals, clinics and first aid stations who use mercurial antiseptics risk inducing such sensitization. *It is significant* that the War Department Technical Bulletin of Medicine (TB MED 147), March 1945, announced the abandonment of local use of any chemical agent in a wound for its supposed antiseptic effect in the prevention or treatment of *infection*.[15]

THE CHEMICAL ASSAULT AGAINST DERMATITIS PEDIS

Since 1916, over a quarter of a century, dermatitis pedis has been subject to topical chemical therapy. It is still being approached from this angle, new "treatment ideas" blossoming out each month. Table 1 contains

a partial listing of the chemicals reported to be of value in dermatophytosis. It is not a chemical classification but more a means of segregation and presentation. An attempt was made to classify pharmacologically these chemicals, but the mass of conflicting data led to abandonment. If one year a certain chemical was found fungicidal and of therapeutic value, the following years it was shown to be worthless. Equally conflicting and depicting the "testimonial treatment idea" was the concentration or strength of topical chemicals. Phenol varied from 1 to 50 per cent, silver nitrate from 0.25 to 20 per cent, salicylic acid from 1 to 40 per cent, mercury bichloride from 1:2,000 to 1:10,000. The proper vehicle to use seemed a matter of yearly trends or whims as well as the chemicals to be incorporated. The tars were praised in some reports, the heavy metals and dyes in others, or the aluminum family and essential oils were superior and finally lemon juice worked wonders. The latest attractions are fatty acids.

Hopelessly mired was the subject of prevention and prophylaxis. Certain writers prescribed a routine as complicated as Hasselbalch's equation and urged Americans to enter the bathroom with a bottle of antiseptic in each hand, to fight contagious, infectious fungi. Other writers called all this useless nonsense and considered it potentially harmful. The fungicidal foot bath passed through its period as a means of prevention to a means of actually spreading infectious fungi. Really to stamp out the dermatophytes it has been proposed that shoes, slippers, stockings and the floors of shower baths and bathrooms be impregnated with fungicidal chemicals. In spite of all these chemical maneuvers the intertriginous dermatophytes failed to yield, so roentgen and radium rays, refrigerants and iontophoresis were brought to bear, aided and abetted by sandpaper, pumice stone and an assortment of knives, scrapers and motor driven burrs. The surgical removal of toe nails and sometimes finger nails has been practiced as necessary, but recently it was proposed that the toe nails—a cosmetic abomination anyway—be permanently eradicated. If the surgeons enter the fight against the dermatophytes, certainly the little toes, perhaps the others and even the foot may be removed: a type of dispatch bound to cure.

Unfortunately this prevention, prophylaxis and therapy frustration has not been kept in the confines of the research laboratory or the sphere of clinical investigation. It has spread into the practices of physicians [16] throughout the country. Certain medical periodicals arriving gratis each month will display eight to fifteen pages of topical preparations, all chemically different but each a specific for dermatophytosis. Pamphlets arrive also with quotations from eminent medical authorities who found this a specific or that a specific "to eliminate fungous infection ringworms without irritation." Furthermore, and herein lies the tragedy, it has spread into the American home. The daily, weekly and monthly periodicals display an urgent message how to diagnose, prevent and treat athlete's foot. The chemicals to choose from in this locality for self treatment are segregated in table 2. A review of the formulas is in reality a chronological treatment history of tinea pedis. Each remedy at one time had an authoritative medical reference. One report, pittanced or commandeered, is sufficient evidence to market and promote a remedy. If later reports fail to substantiate the first, these are ignored. The promotion is diligently fostered, resulting in outdated and discredited chemical hodgepodges, vying for sales appeal on the retail shelves. In a report [17] prepared for the Council on Pharmacy and Chemistry it was stated that only one substance, boric acid, was safe for public use. A canvass by Weidman of his local dermatologic society disclosed that Whitfield's ointment carried a large factor of danger. Twenty-nine of the remedies contained benzoic and salicylic acids. This report considered particularly dangerous preparations containing iodine, mercury, sulfur or sulfonamides. One remedy contained sulfathiazole, six contained sulfur, nineteen contained mercury, nine contained iodine or its compounds. Eighteen of the remedies contained phenol and five ethyl aminobenzoate. These also should be considered dangerous preparations.

---

[16] We were interested in learning the number of dermatologic patients seen by physicians in this locality. A questionnaire was mailed. Over one hundred replies were received. The average was 8 per cent. The diseases of the skin that physicians are called on to care for stands out in sharp contrast to the training given in medical schools. The average from ten schools was 0.016 per cent of the medical curriculum. The comments written in long hand on the replies were critical of the training given and bemoaned its inadequacy.

[17] Weidman, F. D.; Emmons, C. W.; Hopkins, J. G., and Lewis, G. M.: War and Dermatophytosis, J. A. M. A. **128**:805 (July 14) 1945.

THE DIAGNOSIS OF DERMATITIS PEDIS

The symptoms itching, stinging, smarting and burning of the pedal skin indicate that the skin of the foot has become ill. The signs, color, erythema, vesiculation, pustulation, maceration, scaling, fissuring and so on help to indicate the kind and severity of the illness. These symptoms and signs require a diagnosis just as do symptoms and signs referable to the abdomen. The report by Montgomery and Casper [18] describes the signs and incidence of causative fungi in tinea pedis. J. H. Mitchell [19] deplores the tendency to treat all acrodermatitis as ringworm without establishing a diagnosis by microscopic examination. G. M. Lewis [19] adds emphasis to this and considers cultural studies mandatory. Ormsby and Montgomery [20] state that it is essential that the clinical diagnosis be confirmed by a microscopic examination in every case. Dermatitis pedis requires, in addition to the foregoing, a routine blood, urine and serologic examination. Until a diagnosis is made, nursing care of the pedal skin is all that is indicated, and contraindicated are the remedies in table 2. Directing attention to diagnosis and away from treatment will cause a decline in the incidence of overtreatment dermatitis.

COMMENT

Several decades ago the bowel was being symptomatically dosed. Each abdominal complaint had myriads of potions and concoctions all of which, if only given a trial, would effect curative miracles. The bowel has had its therapeutic renaissance, but the skin, its symptoms and even its signs of disease are being symptomatically daubed and painted. A chemical and pharmacologic exposure of the oral cure-alls caused their mysterious and divinatory healing powers to vanish. Many were worthless, others actually or potentially dangerous. When the cutaneous oils, creams, salves, lotions, tinctures and powders are chemically and pharmacologically exposed, many of them will prove worthless. Many are already actually and potentially dangerous. It took the tragedies from self medication to end oral dosing; tragedies from self treatment of skin diseases are mounting. Lane [21] states that improper therapy causes more visits to the dermatologist than any other skin disease, a sad commentary for an era of enlightened therapeutics.

It is urged that the Council "clean house" in the field of cutaneous drugs as it did with oral and parenteral drugs: tear apart the topical concoctions and define each cutaneous chemical in terms of dosage, indications and contraindications, declare each therapeutic agent according to its chemical and pharmacologic properties. If benzoic acid is a useful topical drug, define its dosage —per cent strength—indications and contraindications. If it has no specific uses, it should be discarded. When this is done for each chemical used on the skin, the long lists of prescriptions in textbooks for this or that dermatosis, the host of proprietaries, will be superfluous Physicians will know, depending on the symptoms and signs presented by the skin, the treatment indicated. The proper vehicles should also be defined and kept as simple as possible so that adverse reactions will be more easily apprehended.

Methods of testing cutaneous drugs need definition. Letters arrive weekly from manufacturers stating that their product was tested by an eminent authority and found safe. This is true for the normal skin, whose protective barriers (the p_H, the lipoid coating, the horny mantle) withstood the twenty or forty-eight hour contact; but what about a week or two week contact and, crucially important, the effects of the product on a skin shorn of its protective mantles or eczematized? The product in contact with living epidermal cells, nerve corpuscles and the cutis can be violently toxic, yet harmless when outside the cutaneous protective barriers. The history of this or that remedy helping for a few days, followed by a sudden flare-up, has been consistently noted. All during the course of this investigation it has been disconcerting to see the close similarity between cutaneous medicinals and the chemicals in industry proved to be a leading cause of dermatitis, such as tars, oils, greases, resins, solvents, soaps and alkali.

SUMMARY

The past-treatment patch test in over 400 dermatologic patients showed positive reactions in 40 per cent to one or more of the remedies used.

The chemicals in remedies the most frequent cause of dermatitis were mercury, phenol and ethyl aminobenzoate.

The investigations disclosed that all mercurials should carry a "warning" on the label of the presence of a sensitizer.

The cutaneous tissue reaction denoting sensitization or irritation from topical chemicals has been frequently overlooked and often wrongly considered infection.

Dermatitis pedis requires a differential diagnosis, and to apply or advocate a remedy on the assumption that fungi are the cause promotes and lends countenance to the abhorred practice of daubing.

Lest an episode like table 2 occur again, it is urged that dermatologists take steps to prevent the commercial commandeering of scientific reports and formulas and to set up within present organizations referees working with the Council to judge the maturity of new therapies and diagnostic procedures before they reach untrained hands and produce the treatment tragedies now so evident.

Excellent postgraduate training in the chemistry and pharmacology of topical chemicals awaits physicians who patch test the remedies used—observing the usual precautions—before prescribing further topical treatment.

A vigorous and intelligently conceived educational program setting forth the tenets of preventive and hygienic dermatology, upholding and fostering this program with both hands, not daubing with one, will do much to remove the curse of contactant and overtreatment dermatitis from the skin of Americans.

STREPTOCOCCUS s. b. e. IN SUBACUTE BACTERIAL ENDOCARDITIS

LEO LOEWE, M.D.

C. F. NIVEN Jr., Ph.D., and J. M. SHERMAN, Ph.D.
Associate Professor and Professor, Respectively, of Bacteriology, Cornell University
Ithaca, N. Y.

The subject of the present report is an investigation of organisms recovered from the blood of patients with subacute bacterial endocarditis which were obtained from various sources. The identities of the first 106 consecutive cultures submitted are presented in table 1.

Of interest in this study was the isolation of an apparently new variety of nonhemolytic streptococcus in 41 instances (39 per cent); this organism is now designated Streptococcus s. b. e. Apart from the fact that it had not been recovered or recognized previous to this study, its high incidence warranted intensive investigation. Its cultural properties, relationship to other streptococci and serologic classification were studied in detail.

The significant cultural characteristics of Streptococcus s. b. e. are briefly as follows:

1. Greening occurs on blood agar in twenty-four hours.
2. Hydrolyzes arginine in forty-eight hours.
3. Ferments inulin in one week.
4. Does not ferment raffinose.
5. Does not produce large mucoid colonies on sucrose agar.
6. About 90 per cent of the strains fall in one serologic type, as shown by the precipitin test with cell extracts made according to the Lancefield technic.[1]

Streptococcus s. b. e. is not a miscellaneous collection of "unclassifiables" but apparently a rather homogeneous unit having a unique combination of biologic characteristics as well as considerable immunologic homogeneity. Apart from the washings of an infected sinus, it has not been possible thus far to isolate a similar streptococcus from the human mouth and throat.

This variety of streptococcus not only has a rather characteristic and distinctive combination of physiologic properties but about 90 per cent of the strains which have been tested fall in one serologic type. The few strains thus far studied which do not belong to this serologic type fall in one additional type.

Included in the 41 cases of subacute bacterial endocarditis infected with the new type of streptococcus were a group of 19 patients recruited from a consecutive, unselected series of 102 cases treated with a combination of penicillin and heparin.[2] The refractory character of the organism under investigation is strikingly apparent from a comparative study of treatment statistics, recovery percentage, mortality rate and incidence of recurrence. A forthcoming report [3] deals with the clinical behavior and prognostic import of Streptococcus s. b. e., which was chiefly responsible for the treatment failures (table 2). It was found that intensive, massive penicillin treatment was mandatory in order to terminate the disease in subacute bacterial endocarditis patients infected with Streptococcus s. b. e. The optimum dosage plan for patients thus infected is an uninterrupted span of treatment for eight weeks with daily intravenous administration of at least two million Oxford units of penicillin, the heparin being incorporated in the usual manner. The prompt identification of Streptococcus s. b. e. as the causative agent in subacute bacterial endocarditis, facilitated by the use of the presently available diagnostic serum, has been a life-saving measure.

Table 1.—*Streptococci from Subacute Bacterial Endocarditis*

(106 Cultures from Various Sources)

Species or Variety	Number	Comment
Streptococcus s. b. e.	41	A hitherto undescribed variety of nonhemolytic streptococcus
Streptococcus mitis..........	39	The common throat viridans streptococcus
Streptococcus bovis.........	11	Similar to so-called "Bargen streptococcus"
Streptococcus fecalis........	5	Group D; nonhemolytic enterococci
Streptococcus mastitidis....	4	Group B; 3 hemolytic, 1 nonhemolytic
Group G streptococci........	1	"Nonminute" variety; hemolytic
Unclassified streptococci.....	5	Not identified with any known species

Table 2.—*Streptococcus s. b. e. as a Factor in Prognosis in a Series of 102 Treated Cases of Subacute Bacterial Endocarditis*

Causative Organism	Number of Cases	Treatment Successful		Recurrence	Fatal Outcome
		Number	Per Cent		
Streptococcus s. b. e.	19	8	42	5	7*
Streptococcus mitis..........	17	15	88	0	2
Streptococcus bovis.........	3	3	100	0	1†

Streptococcus s. b. e.: A hitherto undescribed variety of nonhemolytic streptococcus. Strains belonging to this type show distinct homogeneous cultural and immunologic reactions

Streptococcus mitis: The common throat viridans streptococcus

Streptococcus bovis: Similar to so-called "Bargen streptococcus"

* Includes 1 case of terminal Staphylococcus aureus infection following apparent recovery from Streptococcus s. b. e. endocarditis.

† This successfully treated patient subsequently died of congestive heart failure; at autopsy the mutilated valve cusps were completely fibrosed and free from bacteria.

CONCLUSION

A hitherto undescribed type of nonhemolytic streptococcus with distinctive biologic characteristics and considerable immunologic homogeneity has been identified as the causative agent in refractory cases of subacute bacterial endocarditis. The clinical significance of these bacteriologic findings will be the subject of a forthcoming report.

The Level of Lactic Acid in the Brain.—The level of lactic acid in the brain (as found by analysis of tissue frozen in situ) does not passively follow the level in the blood but is regulated primarily by metabolic conditions within the tissue. In morphinized dogs the cerebral lactic acid is increased by hypoxia below a critical level of 11 to 13 per cent oxygen in the respired air. Phosphocreatine begins to decompose below a critical level of 7 per cent oxygen. The lactic acid and phosphocreatine levels also seem to be related to the functional activity of the neurons or the oxidative rate.—Stone, W. E.; Webster, J. E., and Gurdjian, E. S.: Chemical Changes in the Brain and Gasometric Studies of the Blood in Experimental Head Injury, in Trauma of the Central Nervous System, Baltimore, Williams & Wilkins Company, 1945.

NOCTURNAL GASTRIC SECRETION IN DUODENAL ULCER

Studies on Normal Subjects and Patients, with Their Bearing on Ulcer Management

DAVID J. SANDWEISS, M.D.
Detroit

MAJOR MARCUS H. SUGARMAN

CAPTAIN HAROLD M. PODOLSKY
Medical Corps, Army of the United States

and

M. H. F. FRIEDMAN, Ph.D.
Philadelphia

This report deals with 150 nocturnal gastric secretion studies performed on 38 normal persons (73 studies) and 29 patients with duodenal ulcer (77 studies), with particular attention being paid to "hypersecretion" and "hyperacidity" and their bearing on management of patients with duodenal ulcer.

It is generally believed that patients with duodenal ulcer have a more copious secretion of gastric juice (hypersecretion) of a higher hydrochloric acid concentration (hyperacidity) than normal persons of the same sex and age. Both clinicians and surgeons usually focus their attention on this hypersecretion-hyperacid factor in the management of patients with duodenal ulcer. Indeed, a number of gastroenterologists and gastric surgeons, believing that the hypersecretion-hyperacid factor is chiefly responsible for the pathogenesis of both the duodenal ulcer and the postoperative jejunal ulcer, have recommended new ways and means of combating or eliminating this factor. Palmer and Templeton [1] believe that the "excessive continued night secretion" plays an especially important role in the failure of ulcers to heal. They therefore employed radiation therapy over the upper two thirds of the stomach with the view of inactivating the hydrochloric acid producing cells. Connell [2] performed fundusectomy as a method of diminishing the acid secreting surface. Klein [3] and Winkelstein [4] suggested, and Berg [5] and Colp [6] subsequently performed subdiaphragmatic anterior vagotomy along with subtotal gastric resection to prevent the postoperative jejunal ulcers which are being reported in increasing numbers following subtotal gastric resection. They state that hypersecretion of the acid gastric juice is responsible for recurrences following this operation. Recently Dragstedt and his associates [7] performed supradiaphragmatic section of the vagus in an effort to reduce the hypersecretion-hyperacid factor in ulcer patients. Andrus [8] implanted a pedicle graft of jejunum in the wall of the stomach to exert a direct inhibiting effect on the acid secretory mechanism. Ivy [9] and his group are working with enterogastrone, and they [10] and Sandweiss and his associates [11] are experimenting with urogastrone with the hope of controlling the apparent hypersecretory state of ulcer patients.

Because "hypersecretion," "hyperacidity" and the acid gastric juice are generally considered as playing important roles in the pathogenesis of duodenal ulcer and in postoperative jejunal ulcer, we initiated this study to obtain comparative data on patients with duodenal ulcer and on normal subjects.

We conducted our gastric secretory studies during the night, not only because less contaminated gastric juice may thus be obtained for study, but chiefly because we were interested in the concentration and volume of gastric juice during that period of seven or eight hours of the night when normally the stomach is devoid of food and when gastric secretion is uncontrolled. We employed a fairly well balanced meal (which included meat and fish as a source of protein) and gave it at 6 p. m., since this meal given at this time, we believed, would most nearly represent a normal gastric stimulant, and the study would thus most closely represent the normal gastric secretory status during the night. To be more certain of the variations in hydrochloric acid concentration and of the variations in the volume of gastric juice, we obtained hourly samples of gastric juice (from 7 p. m. to 8 a. m.) for titration, complete aspirations of the stomach at the end of each hour from 12 midnight to 8 a. m. and (in other subjects) the total volume of gastric juice from 12 midnight to 7 a. m. by continuous gastric aspiration.

METHOD OF STUDY

Fifty-five night secretion studies were performed on 7 normal young men (19 studies), 8 normal young women (15 studies) and 7 young men with uncomplicated duodenal ulcer (21 studies). All ulcer patients had only mild ulcer distress and presented uncomplicated duodenal ulcers when the studies were conducted. All subjects were ambulatory. All were permitted to have their usual noon meal but not permitted to eat any food until 6 p. m., when their stomachs were completely emptied by aspiration. The volume of the gastric contents were measured and the juice was titrated with 0.01 normal sodium hydroxide for free and total hydrochloric acid, Topfer's reagent and phenolphthalein being used respectively as indicators. Immediately after aspiration the subjects were given an evening meal which was especially prepared. It consisted of foodstuffs which are fairly representative of the average American dietary but which contained a minimum of cellulose. This type of meal was designed to eliminate difficulties in aspiration through the duodenal tube. In addition, the consistency and physical state of the foods were kept constant. This is an important factor in the use of test meals, since Friedman and Pincus [20] have shown

that a difference of as much as 32 per cent exists in the gastric secretory response to a standard meat meal when the meat is ingested as ground beef or as small cubes.

Table 1 lists the various foods of the meal, giving the weight as well as the proportions of protein, fat, carbohydrate and the caloric values. Hourly samples of gastric contents obtained from 8 p. m. until 12 midnight were titrated for free and total hydrochloric acid. At 12 midnight and once hourly thereafter (at the end of each hour) until 8 o'clock the next morning the stomach was completely aspirated, note being made of the volume of juice obtained and the acid concentration of each specimen. The subjects remained in bed at Harper Hospital throughout the night and slept in the interim between aspirations.

To determine what effects meat and fish proteins (when included in the noon meal instead of the evening meal) have on the nocturnal gastric secretions, we conducted 21 additional night secretion studies on the aforementioned 7 ulcer patients with only the following change from the foregoing routine: The meal referred to in table 1 was given at 12 noon instead of at 6 p. m. The 6 p. m. evening meal during these 21 additional studies differed from the other evening meal in that the subjects were allowed no meat extractives (beef broth) and fish, considered to be strong stimulants of gastric secretion. Table 2 lists the nature and amount of each food as well as the protein, fat, carbohydrate and caloric values. We sought to determine whether there would thus be a decrease in the nocturnal volume of gastric juice and a lowering in the acid concentration when the meat extractives and fish were included in the noon meal instead of in the evening meal. The total protein content, however, was practically the same for all of the meals.

In the foregoing 76 studies the gastric juice was aspirated only once hourly from 12 midnight until 8 a. m. We subsequently conducted 74 additional night secretion studies (on 23 normal males and 22 male patients with duodenal ulcer) using the meal listed in table 1 at 6 p. m. but employing continuous suction as the method of aspiration from 12 midnight to 7 a. m. after a preliminary complete emptying of the stomach at 12 midnight. These patients slept undisturbed throughout the night. The reasons for this study will be discussed later.

RESULTS

I. Concentration of Hydrochloric Acid

1. In all instances (chart 1) samples of the gastric contents taken after the evening meal showed a much lower titratable acidity than before the meal. This may be accounted for by both the diluting effect of the meal liquids and the well known neutralizing and acid adsorbing power of the meal solids. It is only after 9 p. m. that an elevation in the gastric acidity usually began to occur; presumably by this time much of the gastric contents have been evacuated. Actually, traces of food were frequently found present in the gastric samples until 11 or 12 p. m. and it is only after this period that the gastric contents can be considered to be least contaminated by food and more truly representative of gastric juice.

2. The curves showing average concentration of hydrochloric acid in both normal persons and ulcer patients show no pronounced variations from each other. After 1 a. m., however, there is a tendency for a higher acid concentration in the normal male group (chart 1).

3. Composite curves showing averages are misleading. A peak in the concentration of acid in one subject (or during one night study) may be leveled out by a low concentration in another subject (or in the same subject on another night), and so on. We therefore present several graphs which we found to represent certain patterns. These are shown in patterns 1, 2, 3 and 4 (charts 2, 3, 4 and 5).

4. As a rule in both normal persons and ulcer patients two and sometimes three peaks in concentration of free acid usually occur, one peak between 10 and 11 p. m., another but smaller peak between 1 and 2 a. m. and a third, still smaller, at approximately 5 a. m. After 5 in the morning the concentration of free acid is nearly always very low (pattern 3, chart 4).

5. At times both in normal persons and in ulcer patients a curve similar to that of pattern 4 is obtained, a rise in the concentration of acid at 9 p. m. reaching its peak at 10 or 11 and remaining approximately at that level until 4 or 5 in the morning.

6. The nocturnal curves of free hydrochloric acid concentration vary considerably. Not only is there variation from one normal person to another and from one ulcer patient to another, but also variations in the same person on different nights, even though the same meal is given at 6 p. m. and the studies are conducted under similar conditions (chart 6).

7. We were able to obtain gastric juice after midnight in all of our 76 studies. In only 2 studies (1 a normal female and the other a male ulcer patient) did the gastric juice fail to show free hydrochloric acid after 12 midnight. In these 2 studies the samples between 8 p. m. and 12 midnight showed free hydrochloric acid.

8. Assuming, as other workers have, quite arbitrarily, that a concentration of over 70 clinical units is abnormal, it will be noted from table 3 that a peak of 70 clini-

cal units or over is found in 53 per cent of the night secretion studies in the normal males, compared with 40 per cent for the normal females, 24 per cent for the ulcer patients with the meat-fish protein diet at the evening meal and 33 per cent for the ulcer patients who had the meat-fish protein diet at the noon meal. If 80 clinical units or over is considered abnormal, then the percentages are 47, 20, 14 and 5 respectively.

On the basis of this small series of subjects and limited number of studies (76 studies) we cannot draw the general conclusion that ulcer patients as a rule have a higher concentration of acid during the night than normal persons.

II. *Volume of Gastric Juice*

(A) Complete Aspiration Once Hourly, On the Hour, from 12 Midnight To and Including 8 A. M. The following summary is presented following an analysis of chart 7 and tables 4 through 7:

1. On the average, a greater volume of gastric juice may be aspirated at the end of each hour from ulcer patients as compared with the average volume obtained from normal subjects (chart 7).

2. The average hourly volume of gastric juice decreases after 11 p. m. until it reaches its lowest level between 5 and 7 in the morning (chart 7).

3. On the average, higher volumes of gastric juice were obtained from ulcer patients as compared with those of normal subjects when the amounts of the eight hourly aspirations for the night were totaled (table 4). In approximately 25 per cent of the ulcer patients we were able to aspirate 300 cc. or more during the eight nocturnal aspirations. In not one of our normal subjects were we able to obtain 300 cc. of gastric juice during the similar eight aspirations (table 5).

4. When the output of free acid is expressed as milligrams of hydrochloric acid it will be noted from table 6 that of the studies on ulcer patients with the meat-fish proteins at the evening meal we obtained 300 mg. of hydrochloric acid or more during the eight night aspirations in 43 per cent of our studies. In 21 per cent of our studies on normal males and in only 10 per cent of our studies on ulcer patients with meat-fish protein foods at noon was 300 mg. (or more) of hydrochloric acid obtained.

5. It will be recalled that following the 6 p. m. meal the stomach was completely aspirated for the first time at 12 midnight. The data show (table 7) that the average amount of gastric contents aspirated at 12 midnight was approximately twice as much for the ulcer patients as for the normal subjects.

On the basis of these data it is apparent that (*a*) at 12 midnight the volume of gastric juice in the stomach of ulcer patients is greater than in the stomach of normal subjects, (*b*) more juice on the average may be aspirated at the end of each hour from the stomach of ulcer patients than from the stomach of normal persons (when aspirations are done hourly) and (*c*) the total volume obtained during the eight nocturnal aspirations is also greater for ulcer patients.

(B) Aspiration by Continuous Suction from 12 Midnight to 7 A. M. In the studies that have been presented, the stomach was aspirated only once each hour during the eight hour period of the night (from 12 midnight to 8 a. m.). As a greater volume of gastric juice was aspirated from patients with duodenal ulcer, the question naturally arose whether the greater volume was due to hypersecretion or whether it was the result of delayed emptying of the stomach. To appraise the latter factor, 74 additional night secretion studies were performed on 23 normal young men (39 studies) and 22 young male ulcer patients (35 studies) using the meal listed in table 1 at 6 p. m. but aspirating the stomach by means of continuous suction from 12 midnight to 7 a. m., after the stomach had previously been completely emptied at 12 midnight. We believed that by this method the factor of delayed gastric emptying, if present, could thus be detected.

The data indicated that: 1. The average volume of gastric juice aspirated from the ulcer patients during the seven hours of the night by continuous suction is approximately the same as that obtained from the normal persons. On the average, 485 cc. of gastric juice was obtained from the ulcer patients and 446 cc. from the normal subjects.

2. One ulcer patient appeared to show a tendency to "hypersecrete." During four night secretion studies on this patient we aspirated 1,143, 1,130, 350 and 1,310 cc. (the third night study was conducted four days after the second study). Were the studies on this 1 patient excluded, the average volumes for the two series of subjects would be 446 cc. for the normal subjects and 383 cc. for the ulcer patients.

3. The average number of milligrams of hydrochloric acid during the seven hours of continuous suction is slightly higher for the ulcer patients (773 mg.) when compared with that of the normal subjects of the same sex (603 mg.). However, when the 4 studies on the 1 ulcer patient who showed a tendency to "hypersecrete" are excluded, the average number of milligrams of hydrochloric acid obtained from the normal subjects is 603 compared with 501 for the ulcer group (tables 8 and 9).

It would thus appear that male patients with duodenal ulcer do not secrete in response to a standard meal a greater volume of gastric juice from 12 midnight to 7 a. m. than do normal male subjects.

COMMENT

I. *On Night Secretion Studies.*—1. Evidence presented heretofore by other investigators has indicated that patients with duodenal ulcer, as a rule, tend to show a hypercontinuous gastric secretion. Our results, however, tend to show that this is not the case with the group of subjects studied by us during the night. Rather, reference to tables 8 and 9 shows that the normal male group on the average has a slightly greater secretion than the ulcer patients of the same sex. The same tendency is noted in the maximum acidity values obtained hourly during the night (table 3) and in the average hourly hydrochloric acid concentration after 1 a. m. (when the data are analyzed statistically the variations between the normal subjects and patients with duodenal ulcer are not significant). However, it must be borne in mind that our series of patients did not present very acute ulcer "attacks" during the course of study.

2. It is of interest to note that the 2 ulcer patients (table 9, cases 2 and 14) in whom we found 2,500 mg. of hydrochloric acid or over during the seven hour period of the night presented more or less intractable ulcers clinically, though no complicating factors were found on physical or roentgen examinations. During the last three years each of these patients has had shorter symptom-free intervals and longer periods of ulcer distress and responded less favorably to medical management. We are wondering whether the hydrochloric acid output in milligrams during the night is of greater

clinical significance than the volume of secretion alone or the concentration of hydrochloric acid alone. More extensive work will need to be done on these and similar patients before definite conclusions may be drawn.

3. It would be difficult to compare our results on nocturnal human gastric secretion with those obtained by other workers. An analysis of their studies shows that each of the authors used a different test meal, gave the meal at different hours of the day or afternoon and aspirated samples of the gastric contents at varying periods of the night. The amounts of gastric juice aspirated by the other workers and the degrees of acidity obtained by them would naturally show variations as compared with ours.

II. *On Medical Management of Ulcer Patients.*—Our present day ulcer regimen aims mainly to combat the acid gastric juice factor. Frequent feedings of bland foods nearly always make up the ulcer diet, not only because these foods are nonirritating and leave the stomach readily, but also because of their neutralizing effect on acid. Meat and fish proteins are eliminated from the diet during the active ulcer period chiefly because of their stimulating effect on gastric secretion. Alkalis or aluminum hydroxide are nearly always prescribed because of their neutralizing effect on hydrochloric acid. Also atropine or belladonna is frequently used not only because of their antispasmodic effect but also because the paralyzing effect on the vagus nerve depresses gastric secretion of neurogenic origin.

There is nothing in our results that conflicts with this regimen. While ulcer patients may not secrete any more gastric juice or hydrochloric acid than normal human beings, our evidence indicates that they retain more of the juice and acid in their stomachs at any one time. This is presumably due to the delay in the emptying of the stomach, probably caused by spasm or edema or by the disturbed intestinal physiology which Berk, Rehfuss and Thomas[24] and Patterson and Sandweiss[25] have shown to exist in patients with duodenal ulcer, or perhaps by flattened or reversed gastroduodenal pressure gradients more recently described by Quigley[25a] and referred to by Ingelfinger.[25b] However, whatever the cause, and regardless of what part hydrochloric acid plays in the etiology of ulcer, it is universally accepted that acid is irritating to the ulcer. Cornell, Winkelstein and Hollander,[15] Dragstedt, Palmer, Schafer and Hodges,[7] Connell,[2] Berg,[5] Colp,[6] Andrus,[8] Ivy and his colleagues,[9] Val Dez,[16] Lannin and Baronofsky,[26] Kiefer,[27] Hinton and Church[28] and many others focus their attention on the acid gastric juice. Palmer[29] states that the free acid is probably responsible for the night pains by its action on the ulcer bed. The acid, therefore, should be neutralized to achieve comfort and to permit healing.

However, the usual regimen is confined to the day, and little attention is paid to the acid gastric juice during the night. In the light of our data it appears to us that, if hydrochloric acid is the chief factor in ulcer distress and delayed healing, more attention should be focused on the nocturnal phase of gastric secretion, regardless of how the ulcer patient "feels" during the night and regardless of the volume of gastric juice and concentration of hydrochloric acid. Free hydrochloric acid in the stomach during the night, even if the volume is less and the concentration is lower, may undo in part what neutralization accomplishes during the day. During the night there is no food in the stomach to have a diluting effect and to act as a neutralizing and adsorbing agent. While an effective gastric secretory depressant is still not available,[30] it appears to us that Winkelstein's[31] continuous intragastric milk-drip method and Woldman and Rowland's[32] modification of the latter by the use of aluminum hydroxide are to date the best means of controlling the nocturnal acid gastric juice. Milk and cream feedings during the night also are effective. These may be administered through a Levine tube while the patient is asleep.

Frequently, particularly in the later stages of the ulcer regimen, the diet of ulcer patients is increased to include meat broths, white fish, white meat of chicken, lamb chops and similar foods. Our data appear to indicate that it is advisable to include these foods in the noon meal rather than the evening meal. The total amount of acid (milligrams of hydrochloric acid) aspirated during the night was less for ulcer patients who had beef broth and fish during the noon hour than those who had these foods at 6 p. m. (table 6).

III. *On Surgical Management of Ulcer Patients.*—During the course of years many operations have been performed in an effort to "cure" patients with duodenal ulcer. Chief of these are gastrojejunostomy, pyloroplasty (Finney, Horsley or Judd type), local excision (cautery or knife), gastroduodenostomy, excision and gastroenterostomy, pyloric excision and gastroenterostomy, excision of the ulcer combined with reconstruction of the pyloric outlet, antral exclusion, fundusectomy, Billroth first and second partial resections, subtotal gastrectomy (Polya and Hoffmeister types), partial duodenectomy and subtotal resection, cholecystogastrostomy, denervation of the adrenal glands and ligation of the gastric arteries (physiologic gastrectomy).

Subtotal gastric resection is the treatment of choice at present when surgery is undertaken. It was at first thought that by subtotal gastric resection achlorhydria would result and the postoperative jejunal ulcer would thus be eliminated. However, recent reports indicate that jejunal ulcer and hemorrhage follow even this procedure. Hurst[33] stated in 1928 "I have seen several cases of secondary ulceration after partial gastrectomy and have collected over a hundred from the literature." (He did not describe the extent of gastrectomy.) Berg,[5] in a series of 225 subtotal gastrectomies for duodenal ulcer, found that 3.1 per cent of his patients developed symptoms due to new ulcerations and that

10.2 per cent of the cases continued with mild general complaints, chiefly "vagotonic" (80.5 per cent of his cases had a follow-up of only one to five years). Colp[6] already reported 40 recurrences following 502 subtotal gastric resections (follow-up one to seventeen years; detailed follow-up not included in discussion). Kiefer,[27] in a series of 173 cases of subtotal resections for duodenal ulcer, found 6.9 per cent of the cases with jejunal ulcers and 4.6 per cent of cases with subsequent hemorrhages, a total of 11.5 per cent of failures following subtotal gastric resections for duodenal ulcer (postoperative follow-up six months to eight years, average between three and four years[33a]). He adds "The hope that this radical operation would solve the problem of postoperative jejunal ulceration, which has brought gastroenterostomy into disfavor, has been displaced by the realization that this complication can follow any operation which joins gastric mucosa to small intestinal mucosa." Hinton and Church[28] analyzed the end results in 97 cases of subtotal resections (average postoperative observation 2.9 years). They report 64 per cent cured and 24 per cent improved (12 per cent failures). Gatewood[34] reported 3 instances in his series of 30 subtotal resections, and Garrett[35] 2 in his series of 26. One of us (D. J. S.) has so far seen 3 cases with recurrences among 13 of his patients who were thus operated on and on whom he had a satisfactory follow-up. Aaron[36] cited a case in which symptoms continued after a gastroenterostomy, later after a partial resection and still later after a subtotal gastric resection. "At the time of the fourth operation the patient had a perforated peptic ulcer just about where the esophagus joins onto the stomach."

More recently Rienhoff[37] reported on the surgical treatment of 260 consecutive cases of duodenal ulcer. He states: "Regardless of the type of operation performed or the operator, where jejunal and gastric mucosa are brought together in the presence of acid chyme a certain percentage of patients will suffer from postoperative complications similar in all respects to the original complications of the primary ulcer for which operation was performed."

Persistence of acid is thought by many to be responsible for the failures following subtotal gastric resection.

Of late, as a result of failure to produce achlorhydria in many of the subtotal gastric resection cases, new surgical procedures have been recommended to control or eliminate the hydrochloric acid factor. Berg[5] and Colp[38] have cut the anterior fibers of the vagus nerve, subphrenically, in addition to the operation of subtotal gastrectomy. Dragstedt, Palmer, Schafer and Hodges[7] recently reported supradiaphragmatic section of the vagus nerves. Andrus[8] has implanted a pedicle graft of jejunum in the wall of the stomach. These operations, as was the case with many of the aforementioned operations, were devised in an effort to decrease or eliminate entirely the acid factor in patients with duodenal ulcer.

However, the fact is that the foregoing newer surgical procedures do not eliminate entirely the acid gastric juice. Winkelstein,[4] Dragstedt and his associates,[7] Klein and his associates[39] and Crohn[40] state that some patients still secrete hydrochloric acid following supradiaphragmatic vagotomy or infradiaphragmatic vagotomy in conjunction with partial or subtotal gastrectomy. Grossman, Dutton and Ivy[41] have shown that implantation of a jejunal flap into the stomach of dogs does not significantly alter the acid secretory response of the stomach to histamine stimulation in the dog. In addition, Kolouch, Dubus and Wangensteen[42] also present evidence suggesting that the jejunal graft is inefficient in controlling gastric and peptic secretion.

If hydrochloric acid plays a major part in the recurrence of duodenal ulcer, and if acidity is responsible for the postoperative jejunal ulcer, then merely decreasing the volume of acid gastric juice and merely lowering the hydrochloric acid concentration are not sufficient to prevent recurrences. During the night the continuous secretion of acid juice, regardless of its volume and its concentration, may still produce its corrosive effect.

With Crohn,[40] therefore, we question whether the results obtained warrant the risk involved in these new surgical procedures. Already Dragstedt and his associates,[7] in their report on surpradiaphragmatic section of the vagus nerves, state that "in 1 patient, similarly operated on in our institution by another surgeon, the ulcer pain recurred together with an active crater." An analysis of the 15 cases more recently reported by Dragstedt and Schafer[43] shows that 6 of the 15 patients continue to have distress. Gastroenterostomies were performed subsequently on 3 of these patients. Their report deals with a follow-up of only one to twenty-one months. Winkelstein[4] claims that cutting the vagus fibers above the diaphragm "may lead to harmful procedures in the abdomen." He advocates cutting the subanterior ones (subphrenically) in addition to partial or subtotal gastrectomy. Crohn,[40] however, states "I have never been convinced that cutting the anterior vagus is sufficiently adequate to warrant its inclusion in the routine operation of subtotal gastrectomy for ulcer. I have seen Dr. Colp, in 2 cases, cut both anterior and posterior vagus nerves above the diaphragm. No material benefit seemed to accrue to the patient, nor was the acidity materially reduced." He adds, further, "Great difficulty is encountered in cutting all of the filaments of both vagi above the diaphragm. To be successful it would require practically a complete circumcision of the esophagus; in 1 case at postmortem it was observed that in spite of the greatest diligence at the time of the operation several intercommunicating fibers between the vagus plexus seemed to remain intact. In 1 case which I observed, a supradiaphragmatic section of the vagus nerves did not clinically benefit a gastrojejunal ulcer."

Weinstein, Colp, Hollander and Jemerin[43a] reviewed the literature on gastric vagotomy and presented their findings in 6 patients on whom vagotomy was performed either alone or in conjunction with some other operation. In 2 of these cases complete vagotomy was attempted. They report that, (*a*) experimentally, little diminution in the nervous phase of gastric secretion is to be expected, while the other (chemical) gastric secretory phases are entirely unaffected; (*b*) in none of the 6 cases was clearcut evidence of beneficial therapeutic effect obtained; (*c*) a definite increase in operative risk and morbidity was encountered; (*d*) partial vagotomy does not influence the nervous phase of gastric secretion significantly, and even if it did, the other secretory phases may overshadow the nervous phase to such an extent as to render it unimportant. They conclude: "Accordingly, gastric vagotomy alone cannot be recommended as a therapeutic procedure: complete vagotomy because of its risk, difficulty of accomplishment, possible effect on motility and only questionable influence on secretion; and partial vagotomy because of the absence of any beneficial effects whatever."

It is to be borne in mind that the secretion of acid gastric juice is only one of many functions under vagus control. The organs supplied by the vagus are numerous and their functions of inestimable value. The action of the vagus on these organs is still not clearly known for man. While the duodenum and the pancreas probably receive vagus nerve fibers by other routes, there is a direct innervation of these organs by branches of the vagus which are sectioned in the foregoing operative procedures. Evaluation of such vagotomy operations on functions such as pancreatic secretion must be made. An additional point to be remembered is the fact that section of the vagus nerve abolishes various reflexes of visceral origin which are definitely protective in character (such as the "receptive relaxation" of the duodenum).

With reference to the Andrus operation, Saltzstein and Kurtz [44] definitely proved that such an implantation, in Mann-Williamson dogs, does not prevent the formation of the typical jejunal ulcers. Of 6 Mann-Williamson dogs with a pedicle graft of the jejunum implanted in the stomach wall, 5 developed Mann-Williamson ulcers; the sixth dog, while not showing a jejunal ulcer, showed a large ulcer in the center of the jejunal flap that was implanted in the stomach.

These experiences surely dictate conservatism when surgery is considered or is undertaken for duodenal ulcer in man.

At present we know of no medical or surgical procedure that will completely eliminate the nocturnal gastric acid factor for any appreciable period of time in all ulcer patients, unless it is total gastrectomy. But even then are we sure that jejunal ulcers might not follow as a result of trauma, tissue susceptibility or ulcer diathesis?

SUMMARY

While the number of studies in our series are too few for definite conclusions, our data on 150 night secretion studies conducted on both normal subjects and patients with duodenal ulcer, nevertheless, warrant the following impressions:

1. Both normal persons and patients with duodenal ulcer secrete acid gastric juice during the night even when the 6 p. m. meal consists of foods usually allowed ulcer patients.

2. Following a fairly well balanced meal at 6 p. m. (which included beef broth and fish) the nocturnal gastric juice from patients with duodenal ulcer is approximately of the same hydrochloric acid concentration as is the gastric juice from normal subjects of the same sex.

3. Following this meal at 6 p. m. the nocturnal volume of gastric juice in patients with duodenal ulcer (as obtained by continuous suction) is on the average not greater than that of normal subjects of the same age and sex.

4. When intermittent single aspirations are performed during the night (not continuous aspiration) a greater quantity of gastric juice is found in the stomach of duodenal ulcer patients as compared with that found in the stomach of normal subjects of the same sex. The greater volume is due, however, not to a state of hypersecretion but probably to a state of delayed gastric emptying.

5. Only 1 of our 22 ulcer patients may be interpreted as probably having a tendency to gastric hypersecretion. More studies by means of continuous suction on both ulcer patients and normal subjects are essential before definite conclusions may be drawn.

6. If hydrochloric acid is the chief factor in ulcer distress and delayed healing, it is essential that more attention be focused on the nocturnal phase of gastric secretion regardless of how the patient "feels" during the night and regardless of the volume of gastric juice and concentration of hydrochloric acid. While ulcer patients may not secrete any more gastric juice or hydrochloric acid than normal persons, our data indicate that ulcer patients retain more of the juice and acid in their stomachs at any one time. During the night, therefore, the free hydrochloric acid in the stomach may undo in part what neutralization accomplishes during the day, as during the night there is no food in the stomach for the meal liquids to have its diluting effect and for the meal solids to perform the neutralizing and acid-adsorbing power. Feedings during the night are therefore essential.

7. When meat and fish are added to the diet of ulcer patients it is advisable to include these foods during the noon meal instead of during the evening meal. When the noon meal (instead of the evening meal) includes these foods, the stomach contains less free acid during the night.

8. Conservatism is advisable when surgery is considered or is undertaken for duodenal ulcer in man.

9739 Dexter Boulevard, Detroit 6.

ABSTRACT OF DISCUSSION

DR. WALTER C. ALVAREZ, Rochester, Minn.: This study is an important one because it has long seemed probable that one of the most important factors in the production of ulcer is the continuance of secretion in the stomach after buffering food has all passed into the bowel and the patient has gone to sleep. The next question is: If the patient with ulcer continues to secrete acid gastric juice after his stomach is empty why does he do it? The answer is to be found in a statement made to me by dozens of wives of men with ulcer who say that the husband is a very restless sleeper who seems usually to be half awake. Often he tosses or groans or talks or grinds his teeth until the wife has to move to a separate room. Many an ulcer patient has told me that half of his brain seems to keep going all night so that he wakes with his day's work all planned. Perhaps, then, it is a characteristic of many men with ulcer that during sleep some lower part of the brain does not quiet down properly but keeps sending off impulses, some of which keep secretion going in the stomach. There are a number of reasons why the observations of Sandweiss and his associates do not agree entirely with the results published in the past. It would seem probable that the essential point in the maintenance of an ulcer is not so much that the titer of the acid be high as that secretion continue after buffering food is gone. One would expect many persons with ulcer not to have a typical hypersecretion, and one would expect to find many "normal" controls to have hypersecretion and a temperament ideal for the formation of a bad ulcer. Probably the only reason why they never get an ulcer is that they fail to get from their ancestors certain genes which are necessary. They are like those thousands of typical epileptic persons who have never had a fit. But with all these difficulties in the way of demonstrating differences between the average secretory curves of the controls and the patients with ulcer, Sandweiss and his associates have confirmed the fact that the person with ulcer tends to go on secreting after his stomach has emptied for the night. This is the important point. One way of combating this tendency and the resultant danger to the person is to have the victim set an alarm clock to wake him around midnight so that he can then take a glass of milk, perhaps with some antacid. If he has trouble going back to sleep he can take a sedative at bedtime. During the day when the man is awake he may feel pain as soon as the acid begins to dig into his ulcer and then he can save himself by taking food. During the night he may go on sleeping until much injury has been wrought. It is disappointing to hear that the operation of cutting both vagus nerves is not always giving the desired result. One would expect most of the nerves carrying pain from the stomach and duodenum to go out to the spinal cord by way of the splanchnic nerves.

[44] Saltzstein, H. C., and Kurtz, I. J.: The Effects of Pedicle Jejunal Transplants in the Stomach on Mann-Williamson Dogs, Surg., Gynec. & Obst., to be published.

Dr. Burrill B. Crohn, New York: The idea that duodenal ulcer patients show a continuous night secretion is more or less an established credo and dates back to early work by Einhorn among others. The interesting point about this paper is not so much the confirmation of the high acidity values and the hypersecretion which is seen in ulcer patients but is the fact that almost identical values were found in normal men and even in some normal women as controls. This point only emphasizes the fact that the ulcer is not attributable to 10 or 20 units of increased acidity or some such figure. Following subtotal gastrectomy, ulcer may recur when even a small amount of free acid is present. Many of the purely functional cases which we included in the old category of Reichmann's disease showed high acid curves and continuous hypersecretion for six hours after a test meal and yet ulcer did not develop. That unknown quantity the x-factor, which disposes to ulcer, is missing in the constitution of these patients. Previous criticisms of these secretory studies have been made on the ground that the complete aspiration of the stomach at midnight acted to discourage further secretory activity during the latter part of the night. Such criticism is not valid since identical conditions prevailed in the study both of the control and of the ulcer cases. The important conclusion from this paper is the necessity for the treatment of the patient during the night by some means, either frequent feedings or continuous drip of milk or of colloidal suspensions, to obtain a neutralization of the night secretion in the ulcer cases. The authors reflect some hesitation in accepting the operation of subtotal gastrectomy for ulcer as a promising procedure. As each year progresses, experience widens; the mortality of the operation has fallen almost to a disappearing point, and the percentage of recurrences remains materially low. In spite of the recurrences, which may range around 4 to 6 per cent, subtotal gastrectomy is the operation of choice and is followed by anacidity or by reduction of acid secretion in over two thirds of the cases. If the supraphrenic bilateral vagotomy can be shown to have a physiologic basis in reducing or eliminating acid gastric secretion in all of its three phases, this would be an ideal procedure in itself and might possibly obviate the necessity for a resection. But further studies on the alterations of gastric secretion following complete and successful vagotomy will be necessary in order to convince physiologists and clinicians of the favorable alterations in gastric chemism following such a procedure and its consequent beneficial effect on the healing of the lesion.

Dr. A. C. Ivy, Chicago: The observations presented in this paper represent a large amount of work as well as thought regarding the design of the various experiments. In work of this type it would appear to be important to keep several factors as constant as possible in the group of patients under study. One of these factors is the nature of the previous meal. The importance of this factor is indicated by the authors' results, which indicate that the acidity of the night secretion of the ulcer patients was greater when the evening meal contained beef broth and fish than when the same meal was given at noon. A second factor is the nature of the medication given with or between the meals. Alkalis frequently cause a "rebound secretion" whereas aluminum preparations do not. Dr. Sandweiss informs me that the only patient in his group that took considerable alkalis was the one (patient 2) who manifested a hypersecretion. A third factor is the state of activity of the ulcer. There is some evidence in the literature showing that the secretory response to an alcohol test meal is less when the ulcer becomes inactive. Dr. Sandweiss informs me that with the exception of the "hypersecretor" the patients they studied were relatively symptom free or the distress was mild and intermittent. A fourth factor is that all duodenal ulcer patients, as shown in the cases in this paper, in the paper of Dr. Dragstedt and in other papers on this subject, do not manifest a prolonged secretory response to stimuli or a high interdigestive secretion. Even under controlled laboratory conditions only approximately 75 per cent of dogs with postoperative jejunal ulcer manifest a definite prolongation of the secretory response to a test meal in regard to the free acidity of the gastric contents. However, such ulcer dogs, as was true in most of the ulcer patients mentioned in this paper, uniformly show an increase in the volume of gastric contents. Our studies on gastric secretion in the ulcer patient have not involved a study of the night secretion. My associates and I have studied the interdigestive secretion in approximately 100 duodenal ulcer patients fourteen hours after the last meal. We have studied the rate of secretion only when the ulcer is in the very active stage. We have found the acid output (volume × free acid concentration) over a period of one or two hours to be on the average approximately 100 per cent greater in duodenal ulcer patients, when the ulcer is active, than in asymptomatic subjects without a history of dyspepsia. However, we find, as others, that some asymptomatic subjects secrete as much interdigestive secretion as patients with an active duodenal ulcer. Thus the factor which I suspect caused the observations of these authors to be somewhat out of line with those of others is that the ulcer in their patients was relatively inactive. The factors of the "rebound secretion" after alkalis and the nature of the last meal has to be considered also, though it is probable that patients may vary considerably in this regard. We need more data than we now possess on the "night secretion" of patients when their ulcer is clinically active and inactive. Since it has, in my opinion, been established that free acidity is one of the chronicity factors in peptic ulcer, the authors are justified in calling attention to the significance of the "night secretion" especially in that group of patients who tend to be refractory to management.

Dr. Walter Lincoln Palmer, Chicago: The authors are to be congratulated on an interesting study of nocturnal gastric secretion. The observations vary somewhat from those obtained by other workers, notably Winkelstein, Val Dez and Mears, in that Sandweiss and his associates have found a higher fasting or nocturnal secretion in normal persons and less evidence of hypersecretion in patients with duodenal ulcer. The discrepancy may be due in part to the fact that the present investigators were careful to pick healthy normal males as their control subjects. It is evident that more work needs to be done on normal postdigestive and fasting secretion. It is clear, however, that the term "hypersecretion" is valid only with respect to the volume of secretion, not concentration of acid. Ivy, Bloomfield and others have considered the higher fasting secretory rates as rather typical of duodenal ulcer. In general this has been my observation also. Furthermore, our unpublished observations and those of Dragstedt also indicate a higher nocturnal secretion in duodenal ulcer than those described in the present paper. The cases studied by Sandweiss and his associates were uncomplicated ones with mild distress, whereas my associates and I have studied particularly the complicated ones, perhaps with more distress. Patient 2, whom the authors class as a hypersecretor and suggest excluding from their series, seems more comparable to those studied by us. There is some evidence that an active painful ulcer reflexly increases both gastric secretion and motility and that the action of the normal irritant (hydrochloric acid) thus tends toward the establishment of a vicious cycle. The implications of the nocturnal secretion in the treatment of peptic ulcer were recognized by Sippy and his associates and have been in the minds of students of the ulcer problem ever since. There is little doubt that the drip methods do give better continuous neutralization of the acid secretion than other procedures. In the case of duodenal ulcer, continuous aspiration of the stomach may accomplish the same result in terms of the p_H at the site of the ulcer. However, neither of these procedures is practicable for long periods, and the treatment of ulcer must be continued for a long time. The authors have rendered a signal service by emphasizing conservatism in the surgical treatment of peptic ulcer and by again calling attention to the importance of the night secretion.

Dr. Marcus H. Sugarman, Detroit: The following pertinent points need to be reemphasized: 1. Most of our ulcer patients had only mild distress at the time the study was conducted. It is possible that patients with very active ulcer symptoms might show a greater volume of nocturnal secretion and a higher acid concentration, as shown by Dragstedt, Palmer and others. 2. Our controls (in the continuous suction study) were perfectly normal healthy males, free from any complaints whatever. This, at least in part, explains the difference between our results and those of Mears. 3. When meat and fish as a source of protein are added to the noon meal instead of to the evening meal, the stomach contains less free acid during the night. In management of ulcer patients therefore it is advisable to add these foods during the noon meal instead of during the evening meal. 4. During the night, hydrochloric acid in the stomach, unless neutralized, may undo in part what neutralization accomplishes during the day. It is therefore suggested that, in the care of patients with acute ulcer distress, feedings be maintained during the night hours. 5. Our studies also indicate that patients with duodenal ulcer, when presenting only mild distress, do not "hypersecrete." While it is true that a greater volume of gastric juice may be aspirated at any time during the night as compared with normal individuals, the greater volume is very likely not due to hypersecretion.

Dr. M. H. F. Friedman, Philadelphia: Viscerovisceral reflexes perhaps may be responsible for the greater secretion shown by the ulcer patient during a period when he has accentuated ulcer distress. As Dr. Palmer has suggested, the acid gastric juice may perhaps act as an irritant to initiate and maintain this reflex hypersecretion and thus establish a vicious cycle. Possibly during periods of distress there is a lowering of the threshold of sensitivity of the duodenum to acid. Drs. Pincus, Thomas, Rehfuss and I found in dogs that introduction of acid in the small intestine decreased or arrested completely the gastric secretion provoked by feeding meat or injection of insulin. This inhibitory effect, however, occurred only when the p_H of the intestinal contents was depressed to 2.5 or lower. Somewhat similar results were obtained in man by Shay and his co-workers. These workers also found that intestinal instillation of acid was less effective in suppressing gastric secretion in the ulcer patient than in normal healthy persons. It is also interesting to learn that Berk, Rehfuss and Thomas found that the duodenal contents after a test meal have a lower p_H in ulcer patients than in normal subjects. Histamine frequently has been suggested as playing a part in the hypersecretion of gastric juice by the patient with an active ulcer. In this connection the observations of Pincus, Friedman, Thomas and Rehfuss are perhaps significant. These investigators found that, whereas gastric secretion stimulated by food or insulin could be inhibited by lowering the intestinal p_H by intraduodenal instillation of acid, secretion stimulated by histamine was not affected at all.

Dr. David J. Sandweiss, Detroit: Dr. Crohn refers to our hesitation in accepting the operation of subtotal gastrectomy for duodenal ulcer as a promising procedure. He states that the mortality of the operation has fallen almost to a disappearing point and that the percentage of recurrences ranges around 4 to 6. While the postoperative mortality is low for the leading institutions of the country, I have been unable to find accurate figures for the country as a whole. It is also important to bear in mind that, exclusive of the 4 to 6 per cent of recurrences (which I believe refer to ulcerations as evidenced by positive roentgen findings), 4 to 5 per cent have subsequent hemorrhages. In addition, there is a group of gastrectomized patients with moderate to severe postprandial symptoms. In the August 1945 issue of *Gastroenterology,* Berkman and Hack say "We have found that recurrent ulceration is not the only possible unfavorable postoperative reaction with which we may be confronted. There still are patients having gastrointestinal symptoms, and some of them are incapacitated to a degree far greater than some patients who have recurrent ulcers." Glaessner in 1940 and Jordan in 1941 discussed the postprandial symptoms. Mateer in 1941 estimated that postprandial symptoms occurred in approximately 14 per cent of his cases. Church and Hinton reported the results of partial gastrectomy in 104 cases. Some of the patients classified as benefited had weakness, loss of weight or anemia after the operation. Miller in 1942 stated that 17 patients of 240 who were improved following subtotal gastrectomy complained of vague symptoms such as weakness, pallor, nausea and loss of weight. Custer, Butt and Waugh made a statistical study of 500 consecutive cases and reported that typical postprandial symptoms which have been designated as the "dumping syndrome" developed in 28 (5.6 per cent) of the 500 cases. Follow-up data were obtained for five to eight years after operation in 24 of the 28 cases. In 21 the symptoms had continued. The symptoms were so severe that they interfered with the work of 10 patients. Six were unable to work and might be classified as gastric cripples. In addition, there is a group of patients who develop pernicious anemia or pernicious anemia-like blood pictures following this operation. When we take all of these facts into consideration (postoperative mortality, recurrent ulceration, subsequent hemorrhages, the "dumping syndrome," inanition and the anemias) one is justified in saying that subtotal gastric resection is not the answer to our ulcer problem, though I agree with Dr. Crohn that, when surgery becomes a necessity, subtotal gastrectomy is the operation of choice at present. With regard to newer surgical procedures, would it not be advisable to check these first experimentally?

PHYSOSTIGMINE FOR MUSCLE SPASM IN RHEUMATOID ARTHRITIS

ABRAHAM COHEN, M.D., PHILIP TROMMER, M.D.
Philadelphia
and
JOEL GOLDMAN, M.D.
Lewistown, Pa.

Following the work of Kabat and Knapp [1] reporting the use of neostigmine in the treatment of muscle spasm in poliomyelitis, our attention was drawn to the problem of muscle spasm in rheumatoid arthritis and allied conditions. The incidence of rheumatoid arthritis is so great and the various forms of therapy so numerous that it should be our purpose to reduce the treatment of this disease to the simplest denominator. Any form of therapy that tends to minimize deformities should be considered worthy of consideration. Our object in this writing is to (1) prevent deformities in rheumatoid arthritis, (2) lessen the severity of deformities already formed, (3) simplify the drug used, (4) lessen the cost to the patient and (5) relieve pain.

From the Arthritis Clinics of the Philadelphia General Hospital and Jefferson Medical Hospital and the special arthritis wards of the Philadelphia General Hospital.

So that there would be no discrepancies as to the uniformity of physostigmine and its administration simultaneously with atropine, hypodermic tablets containing both physostigmine and atropine were obtained. They were supplied by Endo Products, Inc., of New York.

William Levin, Ph.G., chief druggist at the Philadelphia General Hospital, assisted early in this experiment. He obtained and supplied us with physostigmine. Mrs. Marie Craig, physical therapist, Mr. Francis Naselli, physical therapist of the Division of Physical Medicine at the Philadelphia General Hospital, and Mrs. Phyllis Natkow, laboratory technician, helped in the preparation of clinical material for this problem. The nursing staff of the clinics and the wards have been extremely helpful in both institutions.

[1] Kabat, Herman, and Knapp, M. D.: The Use of Prostigmine in the Treatment of Poliomyelitis, J. A. M. A. **122:** 989 (Aug. 7) 1943.

In April 1944 we published a preliminary report[2] on the use of neostigmine in the treatment of muscle spasm in rheumatoid arthritis. The present report, while supplementary, tends to bring to light new facts relative to the use of an old drug. Because of the expense involved in the use of large quantities of neostigmine for a problem of such proportions, it was found necessary to resort to less expensive drugs. Accordingly physostigmine was selected, since it is very closely related in action to neostigmine, both drugs belonging to the group of anticholinesterase drugs.

In our study we find that there were fewer untoward reactions with physostigmine than with neostigmine. The lesser frequency of complaints with physostigmine made for better patient cooperation. We were also impressed with the observation of fewer complaints of pain from local reactions after injection of physostigmine salicylate than after injection of neostigmine methylsulfate. It is because of this and for reasons aforementioned that we have substituted physostigmine for neostigmine in all our studies. As will be noted, physostigmine bears out our original premise in respect to clinical improvement. It relieves muscle spasm and therefore relieves pain in many instances. The relief is common to a large proportion of cases and is frequently encountered within fifteen to thirty minutes after injection. Further studies with neostigmine bromide administered by mouth do not warrant its continued use for this purpose.

There can be no question concerning the existence of muscle spasm and pain on pressure or stretching of the affected parts. One need only to manipulate a joint of the arthritis victim to confirm this. However, these facts have not been emphasized in the cases of arthritis of long standing.

In rheumatoid arthritis there remains a state of spasm of the muscles even though the joint process has become quite inactive. Palpation of the hamstring muscles in an acutely or subacutely inflamed knee joint will demonstrate this. Spasm can also be elicited about other joints. Both the flexor and the extensor muscles are usually involved; however, the deformity that will result is usually commensurate with the force exerted by the most powerful muscle against its antagonist. This of course depends on the extent of the involvement of the muscle or tendon; the more extensive the involvement, the greater the muscle spasm. Should the flexor be the more powerful muscle but the extensor be most involved, the greater pull will be in the direction of the extensor. However, if there is an equal amount of irritation to the two muscles, the deformity will doubtless be in the direction of the more powerful flexor. This spasm is manifested clinically in various types of painful deformities. If this hypothesis is true, relief of such muscle spasm should result in increased comfort to the patient and a consequent diminution or complete prevention of deformities.

In poliomyelitis the so-called muscle spasm has been treated with apparent success by the use of fomentations in accord with the Kenny technic.[3] In subacute and chronic poliomyelitis, neostigmine (prostigmine) has been used with encouraging results by Kabat and Knapp.[1] Our purpose has been to apply the principles set forth by the latter investigators to the muscle spasm accompanying rheumatoid arthritis, fibrositis, bursitis and related conditions.

Kabat and Knapp believe that neostigmine has a direct action on the spinal cord which may be depressing in nature in some instances and stimulating in others, depending on the group of nerves which are acted on. In cases of rheumatoid arthritis, we believe the action is probably depressive, as the muscle spasm is usually promptly alleviated.

Encouraging results with neostigmine in the relief of muscle spasm in rheumatoid arthritis and bursitis, as well as relief of neuromuscular dysfunction in chronic disability resulting from trauma and cerebral thrombosis, were reported by Kabat.[4] Further evidence that muscle spasm is relaxed by the use of neostigmine is reported by Brainerd and his associates[5] and by Fox and Spankus.[6] The role of neostigmine in the treatment of muscle spasm and the mechanism of its action have recently been reviewed.[7]

PROCEDURE

In the special arthritis wards of the Philadelphia General Hospital we have availed ourselves of the opportunity of studying the effects of physostigmine salicylate on muscle spasm in rheumatoid arthritis. One must take cognizance of the fact that bed rest alone will in many instances give a measure of relief from pain and even some relaxation of muscle spasm.

Since controls were necessary, the patient was first given a hypodermic injection of isotonic solution of sodium chloride daily for one week. Joints were measured before and after the period.[8] If a reasonable amount of improvement was not noted, the patient was then given daily injections of 0.6 mg. ($\frac{1}{100}$ grain) of atropine sulfate. Atropine eliminates the unpleasant parasympathetic side effects of physostigmine as well as of neostigmine, and it was our intention to use atropine in conjunction with physostigmine for the relief of muscle spasm. Joints were again measured before and after one week's treatment and the patient was interrogated as regards pain. In the event that treatment thus accorded produced relief from muscle spasm, the same treatment was continued until no more improvement was obtainable. When it was established that saline or atropine injections produced no relief, physostigmine therapy was instituted. The usual procedure was to give 0.6 mg. each of physostigmine and atropine sulfate simultaneously. If no relaxation of muscle was obtainable with this dose, physostigmine was increased to 1.2 mg. ($\frac{1}{50}$ grain).

In this way we felt that we could presume to conclude whether the improvement obtained was coincident with rest in bed, the use of atropine or the physostigmine-atropine combination.

The dose of atropine sulfate was increased or decreased depending on the reaction encountered. In the presence of an unusual amount of dryness of the throat and/or dilatation of the pupils, the dose of atropine was reduced to 0.4 mg. ($\frac{1}{150}$ grain) depending on whether or not relaxation of muscle spasm could be elicited. However, if there was little or no relaxation of muscle spasm, atropine was maintained at the dose of 0.6 mg. while the dose of physostigmine salicylate was increased to 1.2 mg. On the other hand, if the patient complained of dizziness, salivation, pain in the abdomen or nausea, the dose of physostigmine was reduced or the atropine increased as the case may be.

[8] All involved joints were measured in respect to movements, degree of pain, contractures and so on, at weekly intervals throughout the period of study.

Table 1 is a summary of the types and number of cases treated in the arthritis clinics and represents some of those treated in the special wards for arthritis.

Table 2 represents the cases treated only in the special arthritis wards. Opportunity was had in each instance to follow the procedure of controls as already described.

These following cases represent those hospitalized for the purpose of control:

Case 1.—*Felty's syndrome. Duration ten months. History.*—M. B., a woman aged 21, whose chief complaint was "pain and swelling in joints," had been well until ten months before, when she noticed a recurrent pain in the joints of the right hand. This would persist for a few days and remit for a few. Soon she began to have pain in the wrists, elbows, knees and feet. More recently the shoulders and the temporomandibular joints became involved. After about five months the affected joints began to swell, and soon after there was considerable limitation of motion.

Table 1.—*Types and Number of Cases Treated in Arthritis Clinics*

	Number of Cases	
	Improvement	No Improvement
Rheumatoid arthritis	120	33
[illegible]	13	5
[illegible]	10	1
[illegible]	10	1
[illegible]	1	2
Sciatica	2	2
Osteoarthritis of the hip	2	0
Total	149	44

The patient had been under a physician's care throughout the illness. Two and one-half months before entry she went to a hospital, where she was put to bed. She came to this hospital because of her inability to pay for care.

There was nothing of importance in the past medical history except that she had some pain in the joints at the age of 9. This was not accompanied by swelling, nor was it necessary for her to be confined to bed.

Physical Examination.—The patient, who was poorly developed, weighed 82½ pounds (37.4 Kg.). She was cooperative and noncomplaining, though in apparent discomfort. She lay in bed, where she had been for the past three months. The head, neck and chest were normal except that the apex of the heart was at the fifth intercostal space at the midclavicular line, with a soft systolic murmur. The abdomen showed a firm spleen, palpable 3 fingerbreadths below the costal margin. The liver was palpable 1 fingerbreadth below the costal margin.

The left axilla showed three discrete lymph nodes, each about the size of a large almond. Enlarged lymph glands were also palpable in both groins.

The hands showed fusiform swelling of all the fingers. The wrists were swollen moderately. There was limitation of motion of the elbows to about 85 per cent of normal.

There was complete range of motion of the shoulders. The right knee showed 90 per cent of normal extension. The left knee showed 70 per cent of normal flexion. Both knees were swollen and tender. There was no redness. The feet were tender and swollen.

The impression was of Felty's syndrome.

Initial studies revealed a hemoglobin of 11 Gm., red blood cells 3,880,000, white blood cells 5,650, polymorphonuclears 66 per cent, lymphocytes 26 per cent, mononuclears 6 per cent, basophils 2 per cent, hypochromia, blood protein 6.3 mg. per hundred cubic centimeters, albumin 4.2 mg. per hundred cubic centimeters, globulin 2.1 mg. and sedimentation rate 38 mm. (Westergren). Blood and urine studies were otherwise negative. Biopsy of a left axillary lymph node Aug. 28, 1944 revealed probable lymphatic hyperplasia.

Table 2.—*Cases Treated Only in Special Arthritis Wards*

Key: I. S., isotonic solution of sodium chloride; A. T., atropine sulfate; P. A., physostigmine and atropine; N. I., no improvement; I., improvement.

Aside from stiffness and pain in various joints, the patient had a contracture of the right knee. There was distinct spasm of the hamstring muscles. She was placed on a hard surface, and flexion and extension were measured by estimating the distance from the medial surface of popliteal space to the hard surface. The hamstring muscles were spastic. For one week the patient received a daily sterile hypodermic without benefit. During the second week the patient received a hypodermic injection of 0.6 mg. of atropine sulfate daily without benefit.

Physostigmine salicylate 0.6 mg. with atropine sulfate 0.6 mg. was administered daily by hypodermic from then on. The result obtained is illustrated in table 3, using the measurements of the right knee only.

On September 25 it was decided to replace the physostigmine-atropine by a sterile hypodermic. The relaxation persisted for a few days and the muscle spasm returned. The flexion deformity now measured the same as on September 11. When physostigmine-atropine therapy was resumed, the muscle spasm promptly disappeared. Under this therapy the patient noted that there was decided improvement in stiffness and pain. However, since the improvement in the contractures seemed to be at a standstill, it was felt that additional therapy was necessary for the relief of the rheumatoid arthritis.

A transfusion of 500 cc. of whole blood was given. Because of the weight loss, insulin 5 units three times daily after eating was administered. Eight weeks later the patient weighed 100 pounds (45 Kg.). The blood count was hemoglobin 12.5 Gm., red blood cells 4,000,000, white blood cells 6,100. The patient was very much improved.

Table 3.—*Measurements of Right Knee in Case 1*

Date	Flexion, Inches	Extension, Inches
9/11/44	11	2¾
9/13/44	11½	2
9/15/44	12	1½
9/17/44	11½	1
9/19/44	12	¾
9/21/44	10¾	½
9/23/44	11¾	⅝
9/25/44	12	⅝
9/27/44	11	¼
9/29/44	11¾	¼

Gold therapy was now instituted. This consisted of 1.24 mg. of aurothioglucose 10 mg. given intramuscularly semiweekly for four doses, 25 mg. semiweekly four doses, 50 mg. semiweekly four doses and 100 mg. weekly nine doses. The course was completed Jan. 19, 1945. At that time the patient was free from discomfort. Aside from spindle shaped deformities of the fingers, for all intents and purposes she had made a complete recovery. The spleen was no longer palpable; however, glands were still palpable in the axilla. At the present time she is getting a second course of gold. She is working at her former position and weighs 113 pounds (51 Kg.).

On May 15 there was no evidence of enlarged spleen, and the axillary and inguinal lymph nodes were no longer palpable. The condition of the patient is excellent. Her weight is 117 pounds (53 Kg.).

Case 2.—*Spondylitis of fifteen years' duration. History.*—R. M., a man aged 44, seen March 16, 1945, complained of pain in the back extending from the neck to the lower part of the back and down the legs. He had had pain in the back off and on for fifteen years. At the onset, which was gradual, there were soreness and stiffness in the lower part of the back. This was growing progressively worse until a brace was resorted to. In about six months the patient made a "complete recovery." A few months later the same condition returned and he had grown slowly but steadily worse. He attended various clinics throughout the country, where he was given intensive physical therapy, orthopedic appliances and even a bone graft without relief.

Physical Examination.—This was essentially negative except for a spondylitis. The height was 5 feet 6 inches (168 cm.), while the patient stated that his normal height was 5 feet 9½ inches (175 cm.). He was round shouldered. Examination of the back showed extreme muscle spasm extending from the cervical to the lower dorsal region. The neck showed only about 30 per cent of normal range of motion laterally. Extension was nil, while the head was in the position of flexion. The patient stated that he got but little sleep because of pain. He had to use three large pillows in order to feel one against his head. Examination of the secretion from the prostate gland showed myriads of pus cells.

Laboratory studies revealed hemoglobin 98 per cent, red blood cells 4,920,000, white blood cells 7,000, sedimentation rate 35 mm. (Westergren), blood urea 9 mg., blood uric acid 2.8 mg., reaction of urine alkaline, albumin a trace, microscopically little amorphous phosphate, very occasionally a red blood cell per high power field and 30 to 40 white blood cells per high power field. X-rays of the spine showed arthritic changes of the cervical, thoracic and lumbar spines. There was considerable lordosis present. The lumbar vertebrae showed a bone graft on the left extending from the first to the fourth lumbar vertebrae.

Treatment.—The patient was seen daily for three days and a placebo was given hypodermically. Since he had allotted himself only ten days in the city, it was decided to forego the use of atropine alone and initiate treatment with physostigmine and atropine. Up to this period there had been no improvement. The patient was given 0.4 mg. of atropine sulfate and 0.6 mg. of physostigmine salicylate hypodermically. The following day he reported that all day long he had felt "freer" and had much less stiffness. His height now measured 5 feet 6½ inches (168 cm.). The same treatment was accorded the patient daily. At the end of another week he was able to sleep without medication other than the aforementioned and he was free from pain. His height now measured 5 feet 8 inches (172.7 cm.). Motion in the neck was increased to about 50 per cent of normal for side and side motion. Extension was much improved, and the patient now possessed the ability to flex the head somewhat. He was instructed as to the procedure and told to get an injection daily for one month.

At the end of one month the condition was the same. He was free from pain, slept well and was able to conduct his business as he had not been able to do in years. The height remained at 5 feet 8 inches.

Two and one-half months after the beginning of treatment the patient reported that he felt fine. He was free from pain. His height was the same. He received treatment as described every other day.

Case 3.—*Sacroiliac arthritis with sciatica of twelve years' duration.* E. A., a white woman aged 66, seen July 26, 1944, complained of pain in the back of the left leg radiating down to the calf. The present illness dated back almost twelve years. The condition came on gradually and had been becoming worse until when she was seen the discomfort was intense. The patient had had a breast amputation three years before. She had diabetes controlled by insulin. Her blood pressure was 160/100 mm. She was arteriosclerotic with avitaminosis. Her pain was affected by the changes in the weather.

Examination of the left leg revealed a shortening of the head of the gastrocnemius muscle. There was considerable difficulty in flexion of the leg, and descending the stairs caused much discomfort.

She was given physostigmine salicylate 0.6 mg. with atropine sulfate 0.4 mg. by hypodermic injection. Fifteen minutes later she was able to raise the right knee without discomfort.

Subsequent treatment consisted of semiweekly to weekly injections for a period of about four months. The patient had much relief at night, was able to raise the right leg without pain and could cross her knees and descend stairs easier and without discomfort. There was no difficulty in sleeping.

For the next six months she received injections every two to three weeks or whenever muscle spasm recurred. At no time have her symptoms recurred to the pretreatment state.

Other than a slight facial flushing after the first injection, no drug reactions occurred.

Case 4.—*Rheumatoid arthritis of three years' duration.*—S. D., a man aged 71, had involvement of the shoulders, elbow, hands, right rip and both sacroiliac joints. With the right hand he was able to reach the right eye with difficulty and pain. With the left hand he was able to reach the left ear with difficulty and pain. There was a contracture of the right elbow of 130 degrees and of the left elbow of 120 degrees. There was practically no motion of the right hip.

After one week of daily injections of isotonic solution of sodium chloride and one with atropine sulfate 0.6 mg. there was no improvement. Ten minutes after the hypodermic injection of 1.2 mg. of physostigmine salicylate and 0.6 mg. of atropine sulfate the patient was able to reach the top of his head with the right hand and about 2 inches above the top of his head with the left. He noticed "considerable loosening up" and insisted that this was the first time anything had been given him that didn't put him to sleep and yet gave so much relief from pain.

Treatment was suggested as described to be administered daily for two weeks and then two times weekly. To date, July 10, 1945, the patient has retained the improvement and contractures are gradually becoming less. He has been more comfortable and is able to get around with greater ease.

Case 5.—*Osteoarthritis of hip of fifteen months' duration.* I. M., a white woman aged 53, seen July 28, 1944, complained of pain in the right knee. At the age of 9 she fell, twisting the right hip. Weights were used for treatment. She had been perfectly well until Jan. 1, 1944, when she began to have pain in the right hip following the use of a knee press. The pain was quite severe and radiated down the leg.

The patient, who weighed 193 pounds (87.5 Kg.) and was 5 feet 9 inches (175 cm.) tall, showed limitation of motion in the right hip. Manipulation produced severe pain. The muscles surrounding the hip joint were in evident spasm. Voluntary hip flexion was limited to 200 degrees (180 plus 20). X-ray examination at this time revealed that the hip was gone and no socket was present. The hip joint was obliterated: osteoarthritis (fig. 1).

The blood count revealed hemoglobin 72 per cent, red blood cells 3,680,000, white blood cells 9,250. The patient had been on a weight reducing diet.

Further treatment consisted of physostigmine salicylate 0.6 mg. and atropine sulfate 0.6 mg. hypodermically twice weekly for fourteen weeks and then weekly for nineteen weeks. Following this the patient had considerable relief from pain and the muscle spasm was diminished. Voluntary motion now reached 230 degrees (180 plus 50). Subsequent observations revealed subjectively "that something felt as if it had gone back into place in the hip joint."

Injections twice weekly were sufficient to keep the patient relieved of pain and permitted her to do her own housework without too much difficulty. In all, there was reduction in weight from 193 pounds (87.5 Kg.) to 164 pounds (74.4 Kg.), a weight loss of 29 pounds (13 Kg.) in ten months. At the present time treatments consist of physostigmine-atropine injections weekly and a weight reducing diet.
